Jim Kurose, Keith Ross  
Pearson, 2020

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- **Principles of reliable data transfer**
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

# Principles of reliable data transfer

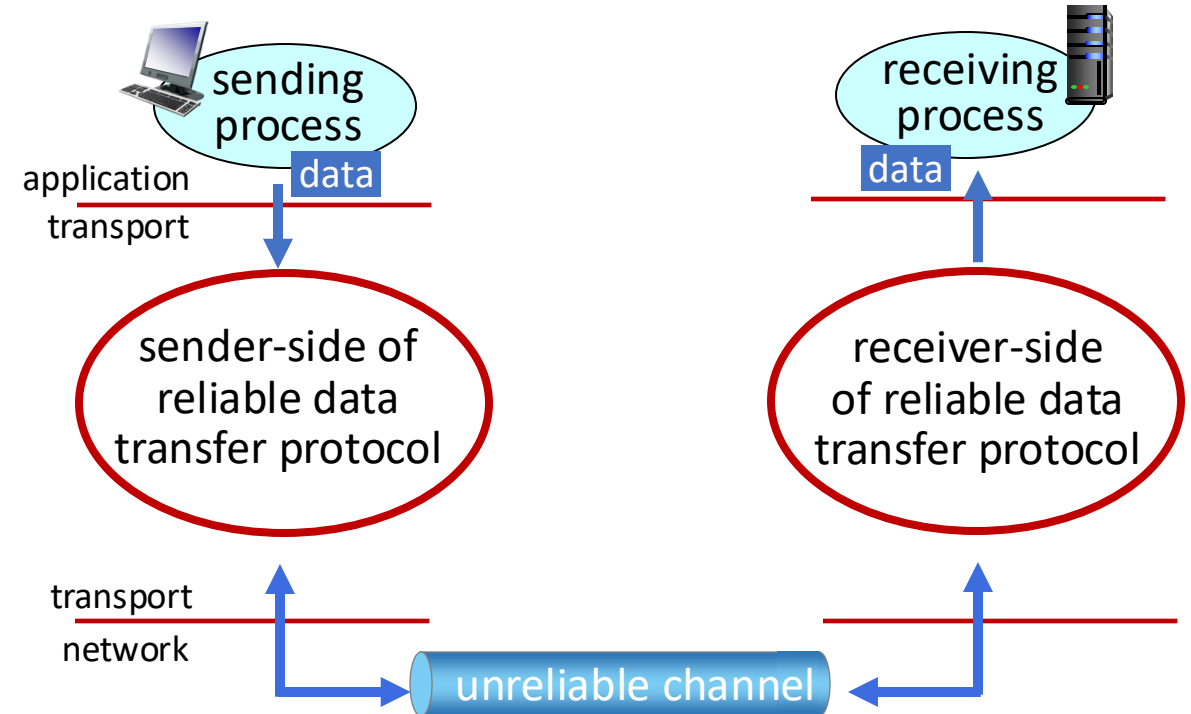

reliable service *abstraction*

# Principles of reliable data transfer

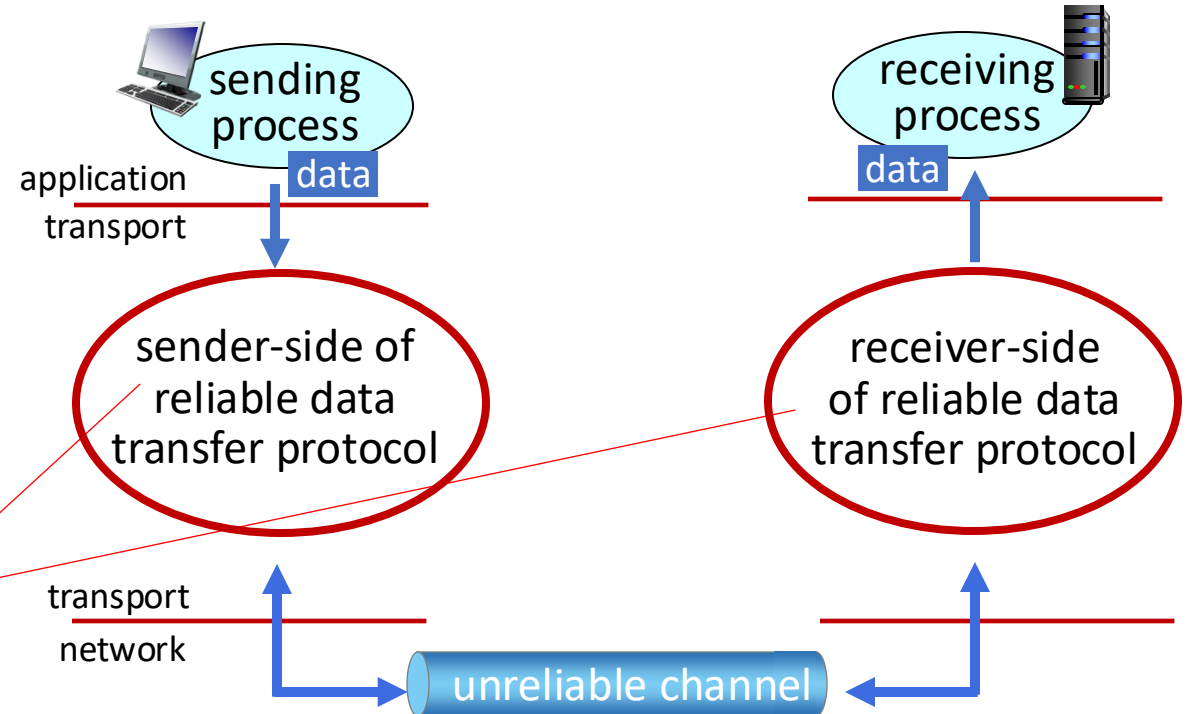

reliable service *abstraction*

reliable service *implementation*

# Principles of reliable data transfer

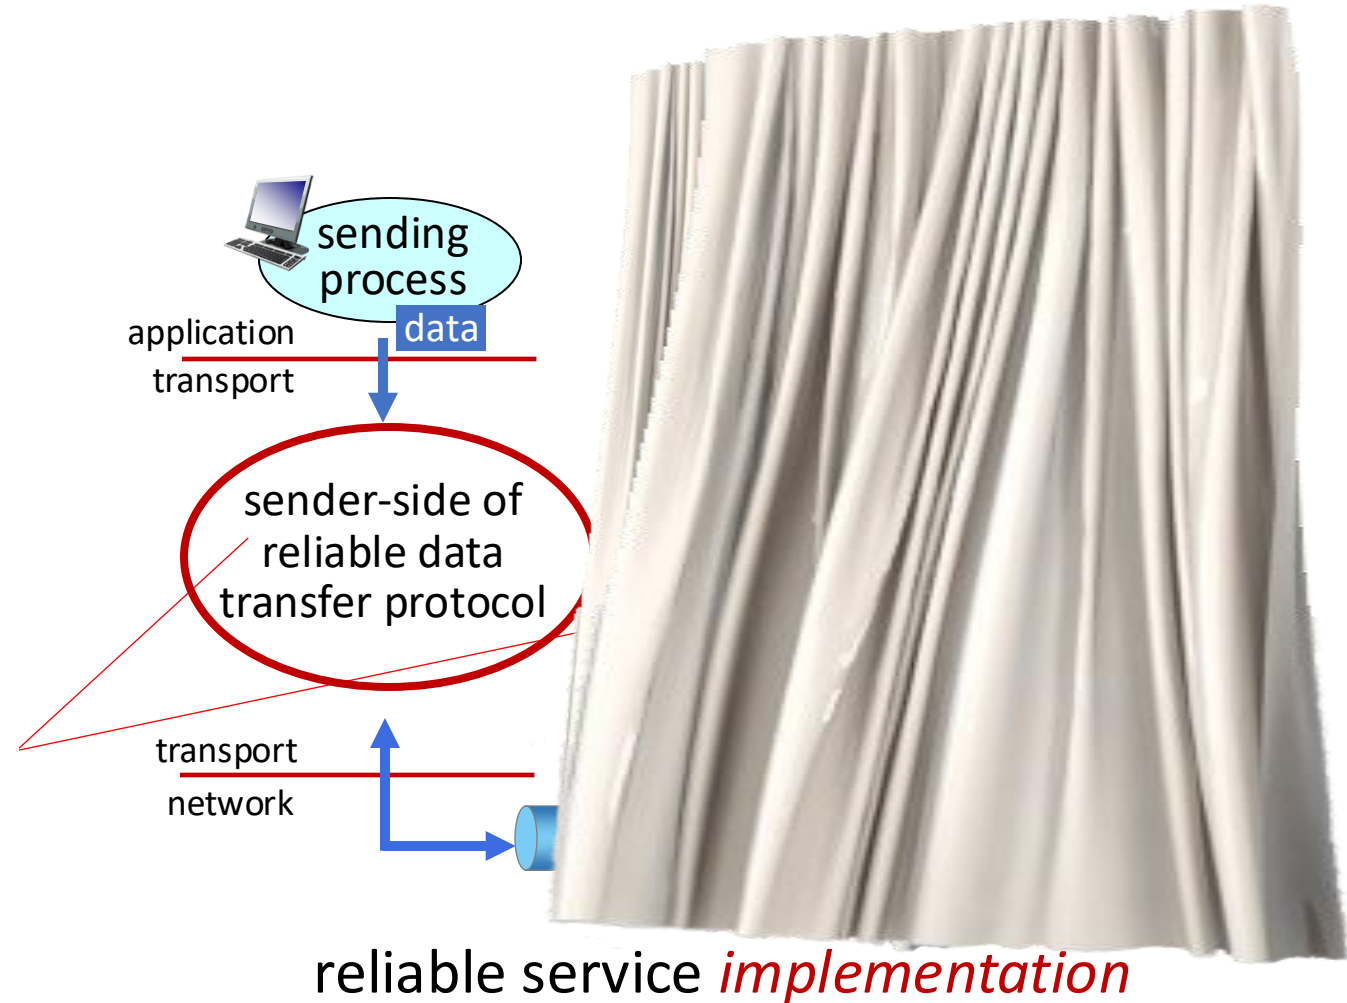

Complexity of reliable data transfer protocol will depend (strongly) on characteristics of unreliable channel (lose, corrupt, reorder data?)

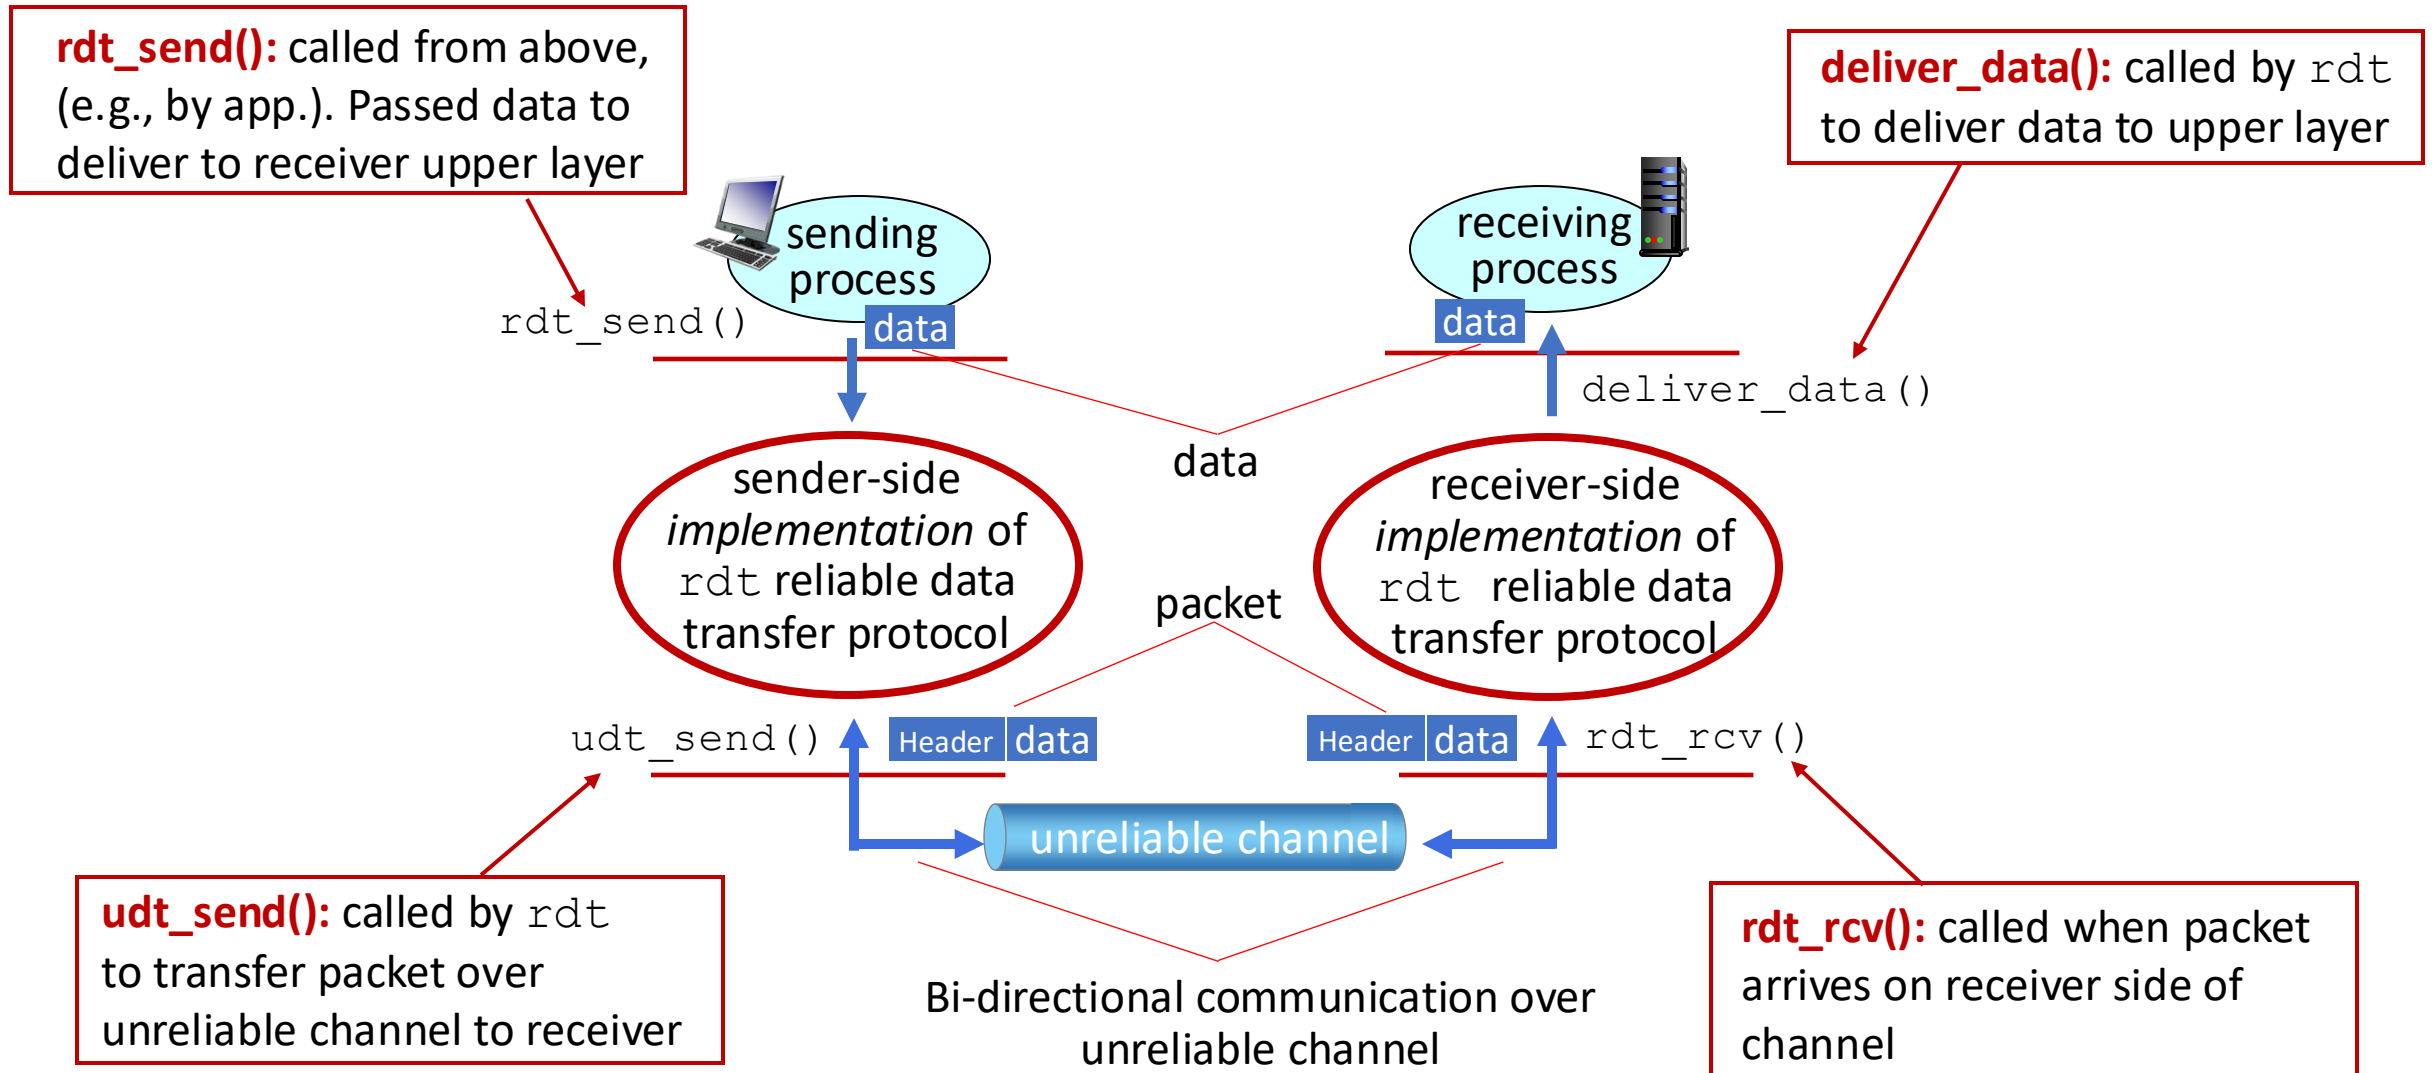

# Principles of reliable data transfer

Sender, receiver do *not* know the “state” of each other, e.g., was a message received?

- unless communicated via a message

# Reliable data transfer protocol (rdt): interfaces

# Reliable data transfer: getting started

## We will:

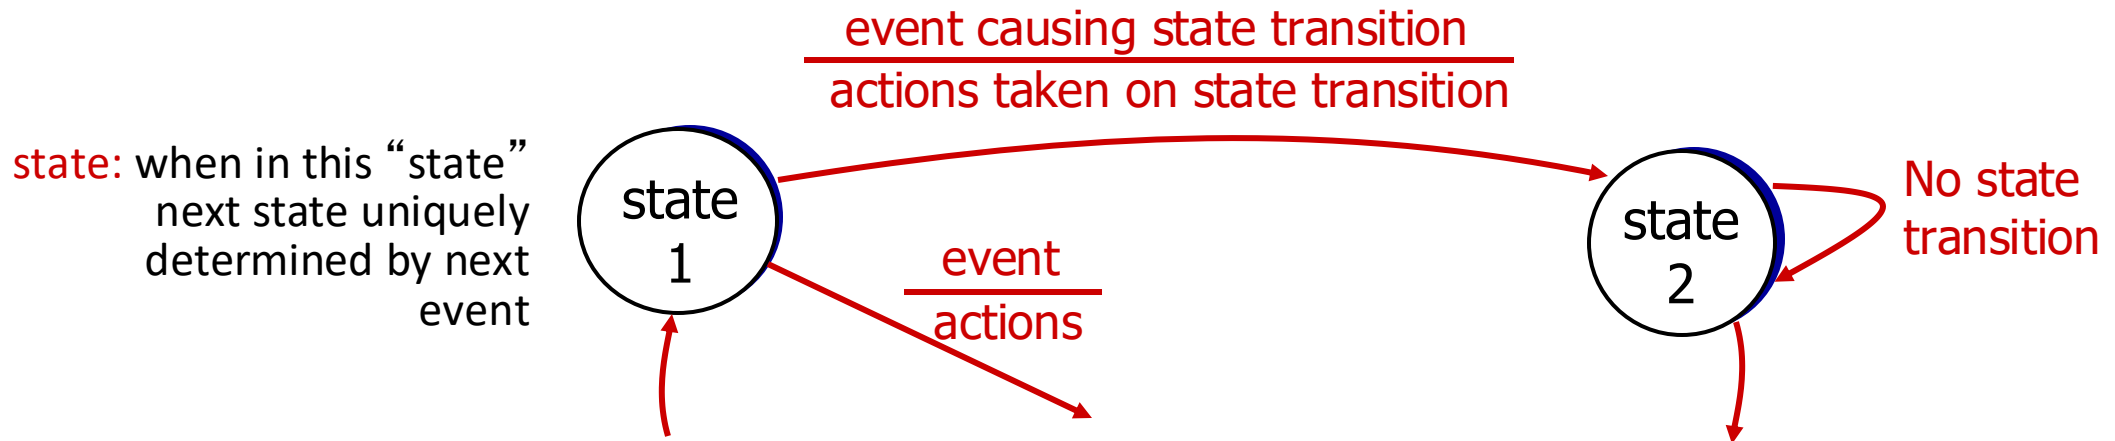

- incrementally develop sender, receiver sides of reliable data transfer protocol (rdt)
- consider only unidirectional data transfer
  - but control info will flow in both directions!

# Reliable data transfer: Protocol States

- use finite state machines (FSM) to specify sender, receiver

# Channel model: Reliable Channel

reliable service *abstraction*

- underlying channel perfectly reliable
  - no bit errors
  - no loss of packets

# rdt1.0: reliable transfer over a reliable channel

- *separate* FSMs for sender, receiver:
  - sender sends data into underlying channel
  - receiver reads data from underlying channel

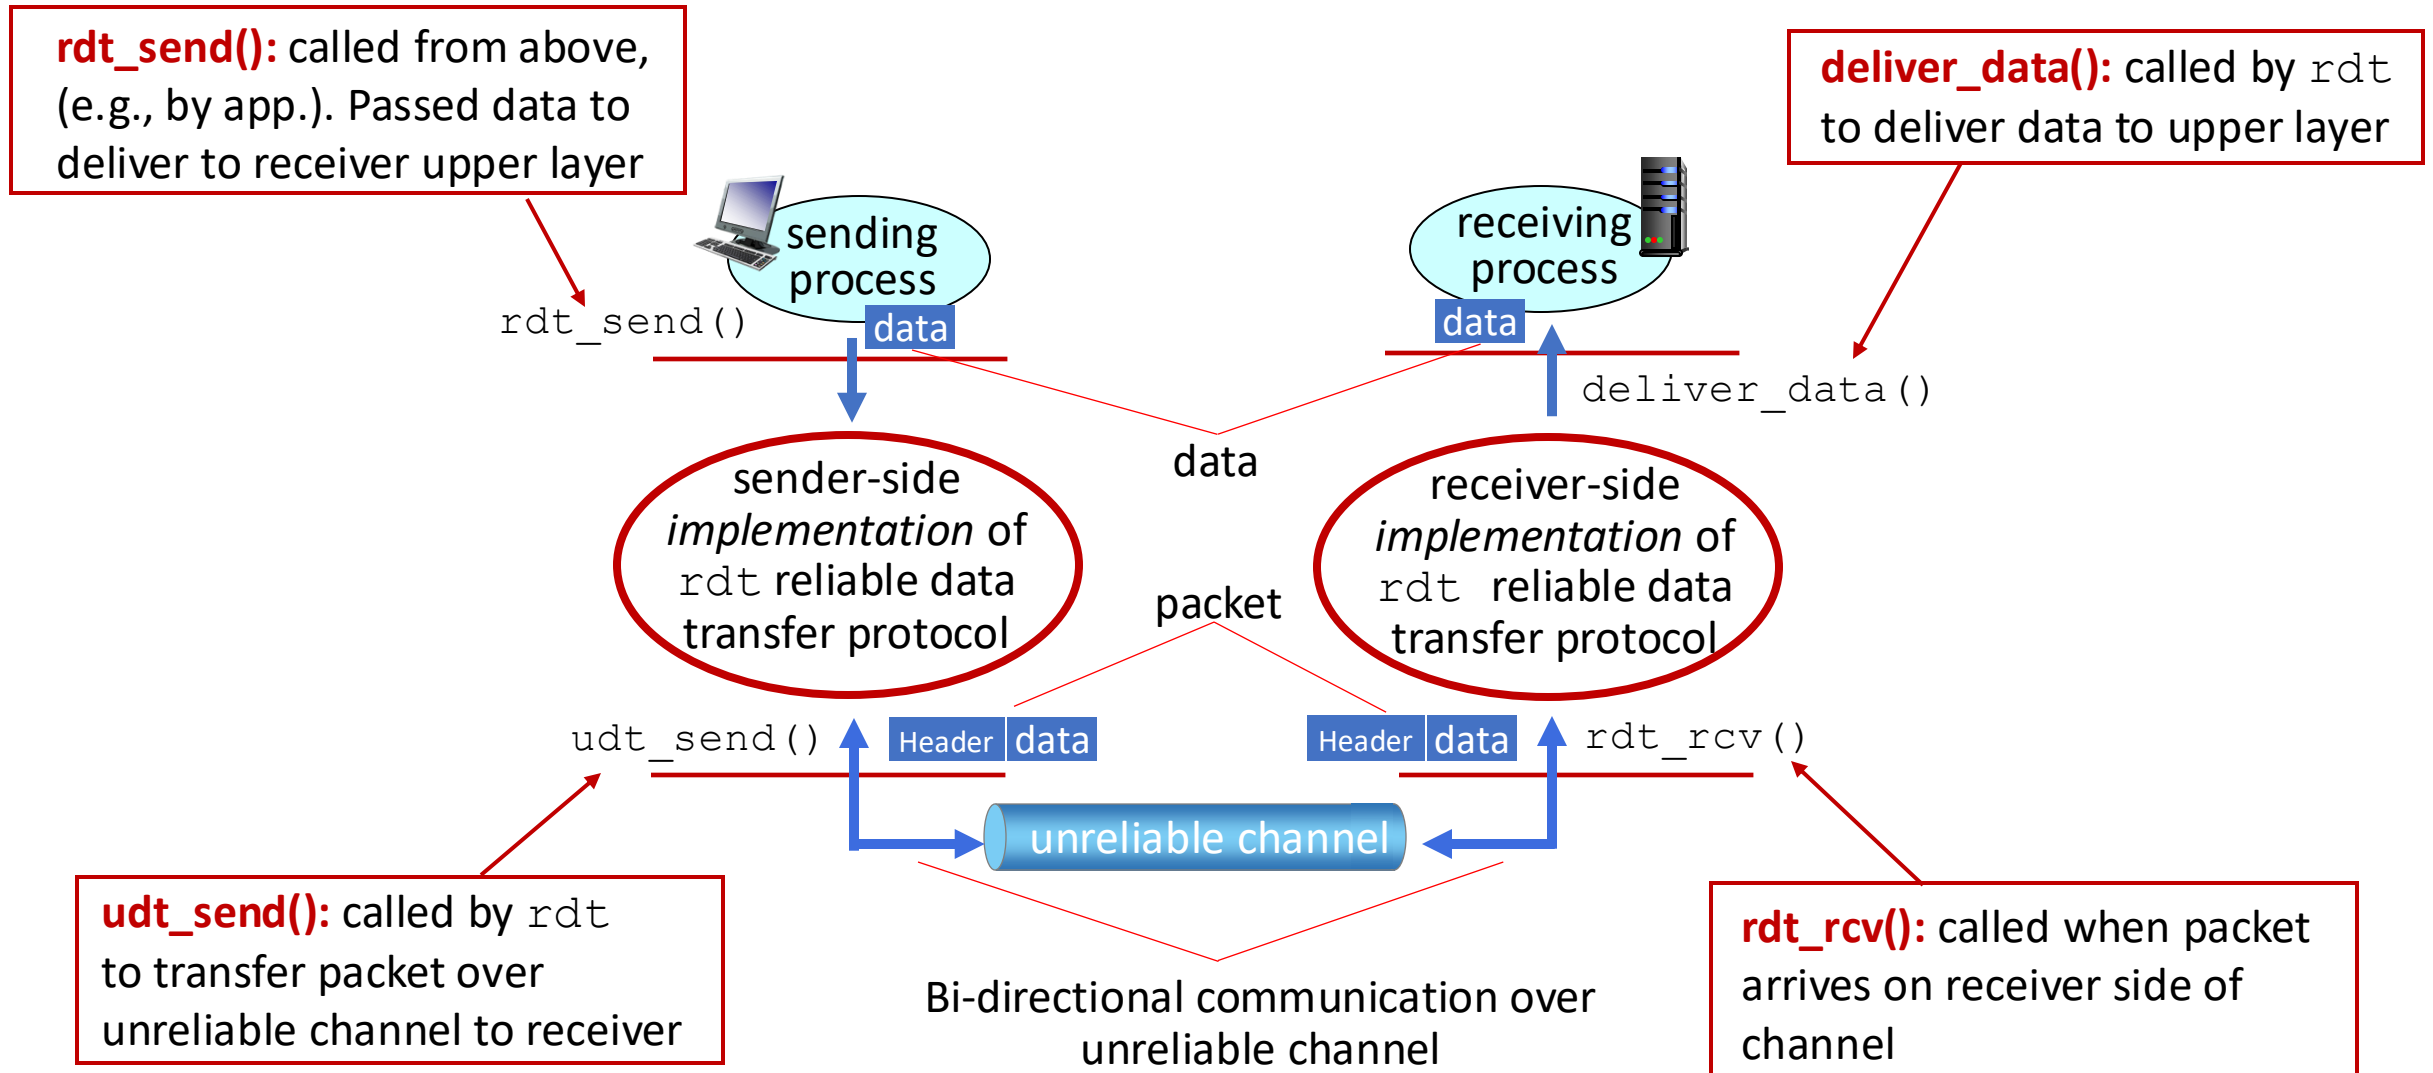

# rdt1.0: reliable transfer over a reliable channel

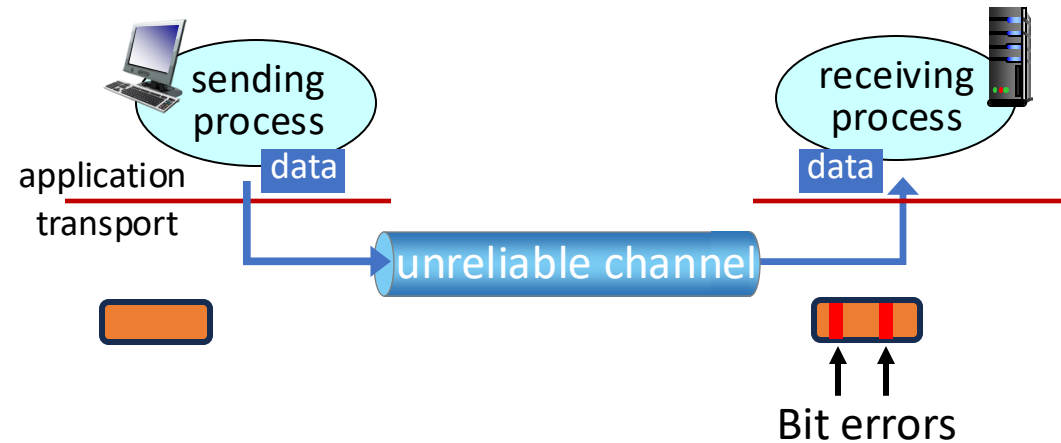

- *separate* FSMs for sender, receiver:
  - sender sends data into underlying channel
  - receiver reads data from underlying channel

# Reliable data transfer protocol (rdt): interfaces

# Channel model: channel with bit errors

- underlying channel may flip bits in packet
  - checksum (e.g., Internet checksum) to detect bit errors

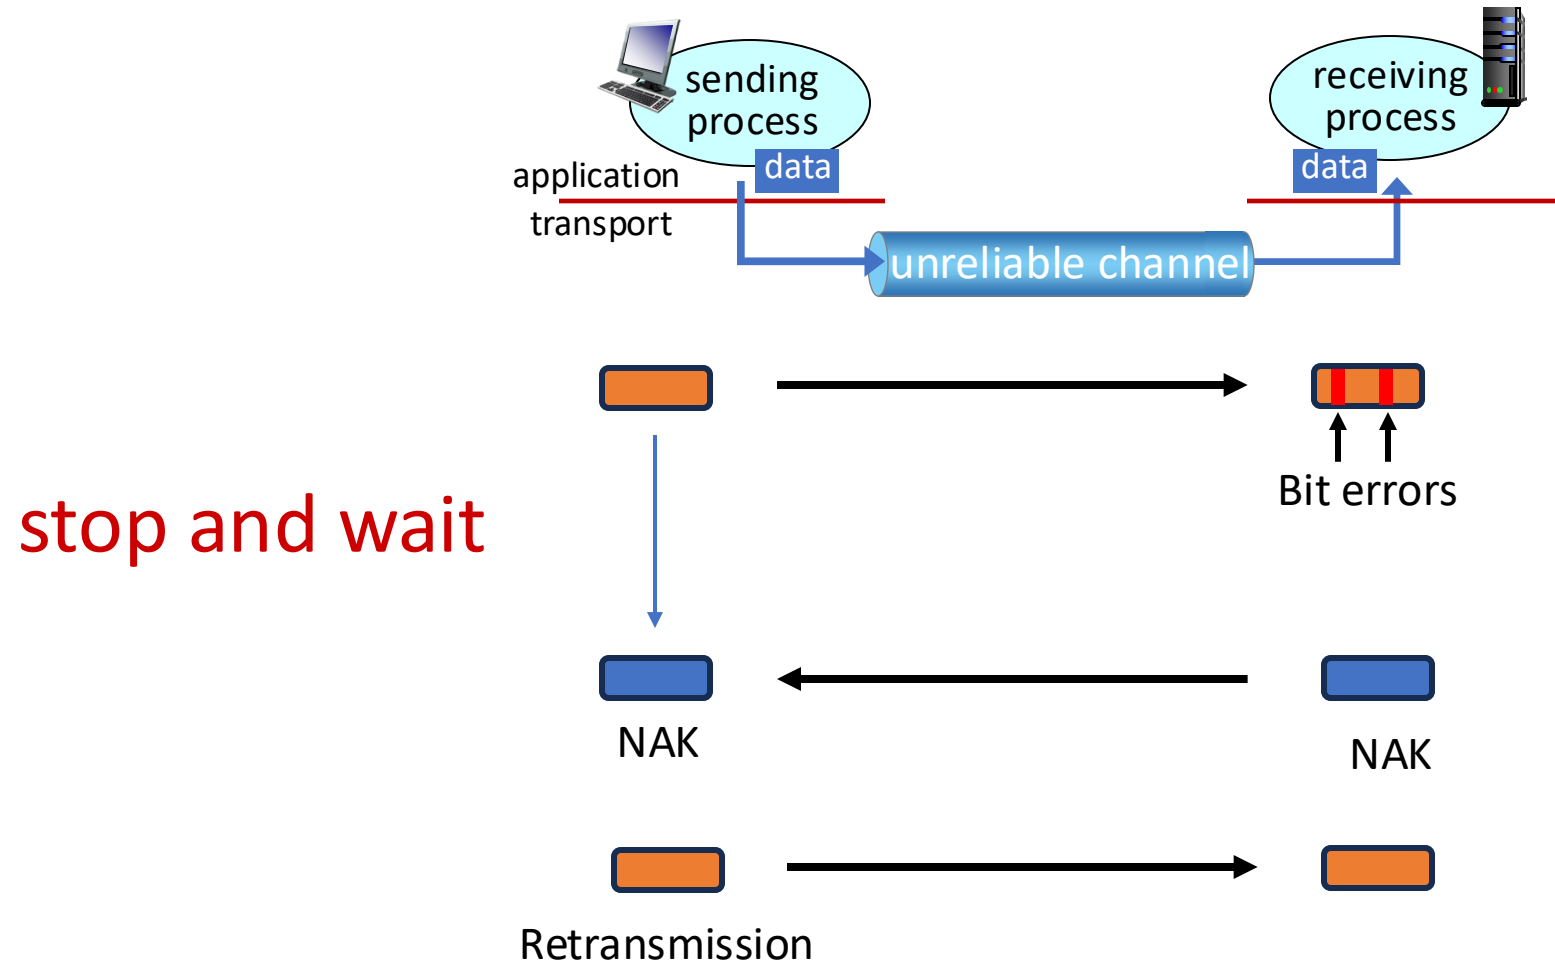

# rdt2.0: channel with bit errors

- underlying channel may flip bits in packet
  - checksum to detect bit errors
- *the question*: how to recover from errors?
  - *acknowledgements (ACKs)*: receiver explicitly tells sender that pkt received OK
  - *negative acknowledgements (NAKs)*: receiver explicitly tells sender that pkt had errors
  - sender *retransmits* pkt on receipt of NAK

— **stop and wait** —

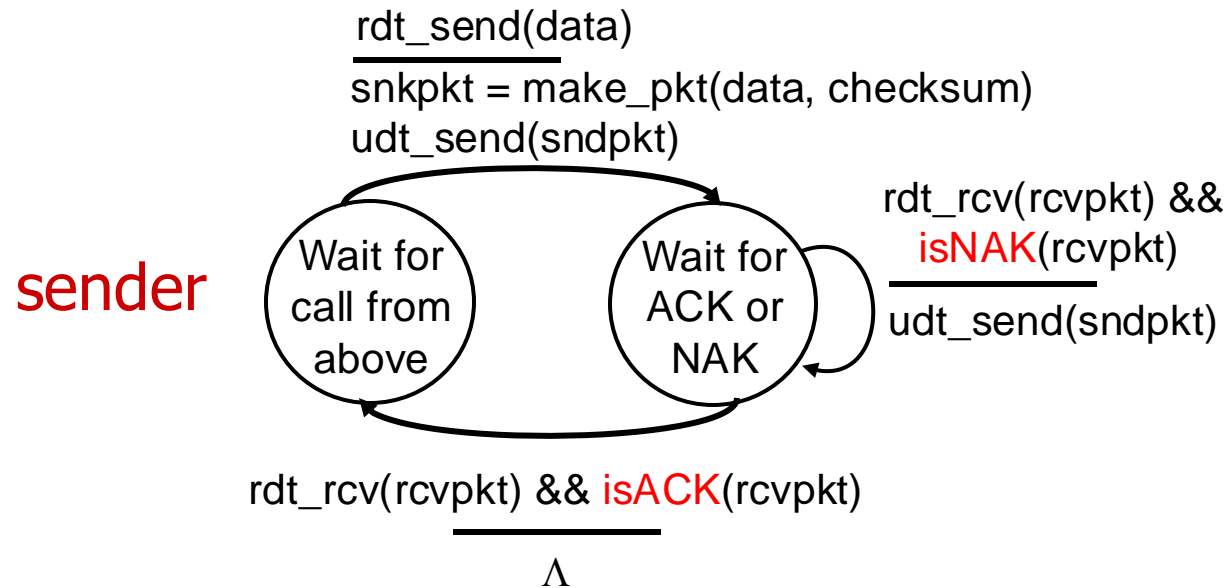

sender sends one packet, then waits for receiver response

# rdt2.0: channel with bit errors

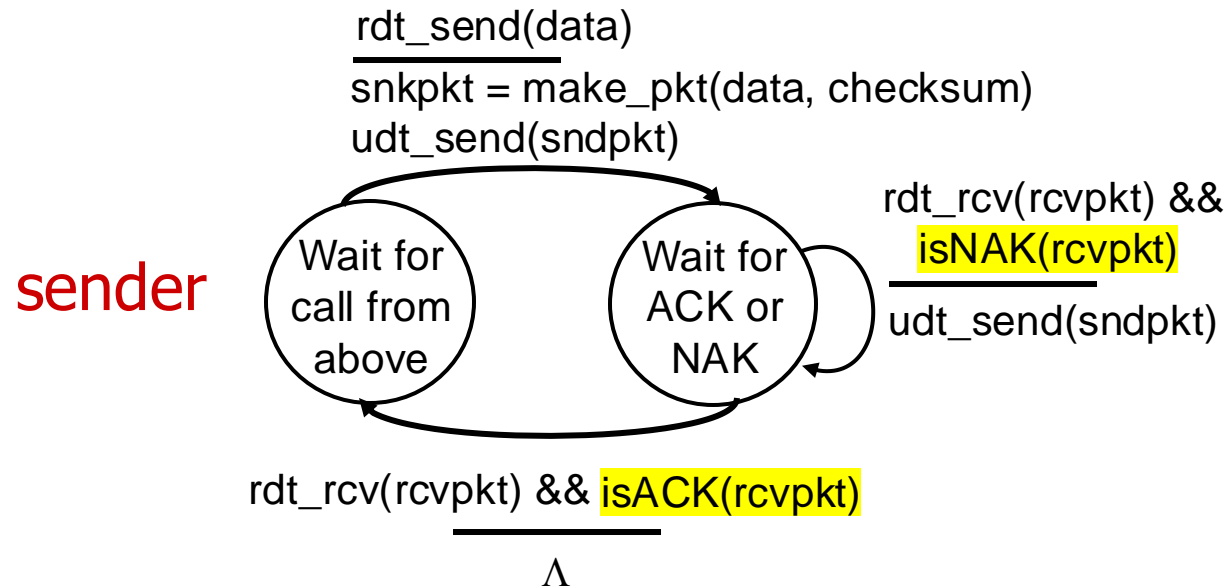

# rdt2.0: FSM specifications

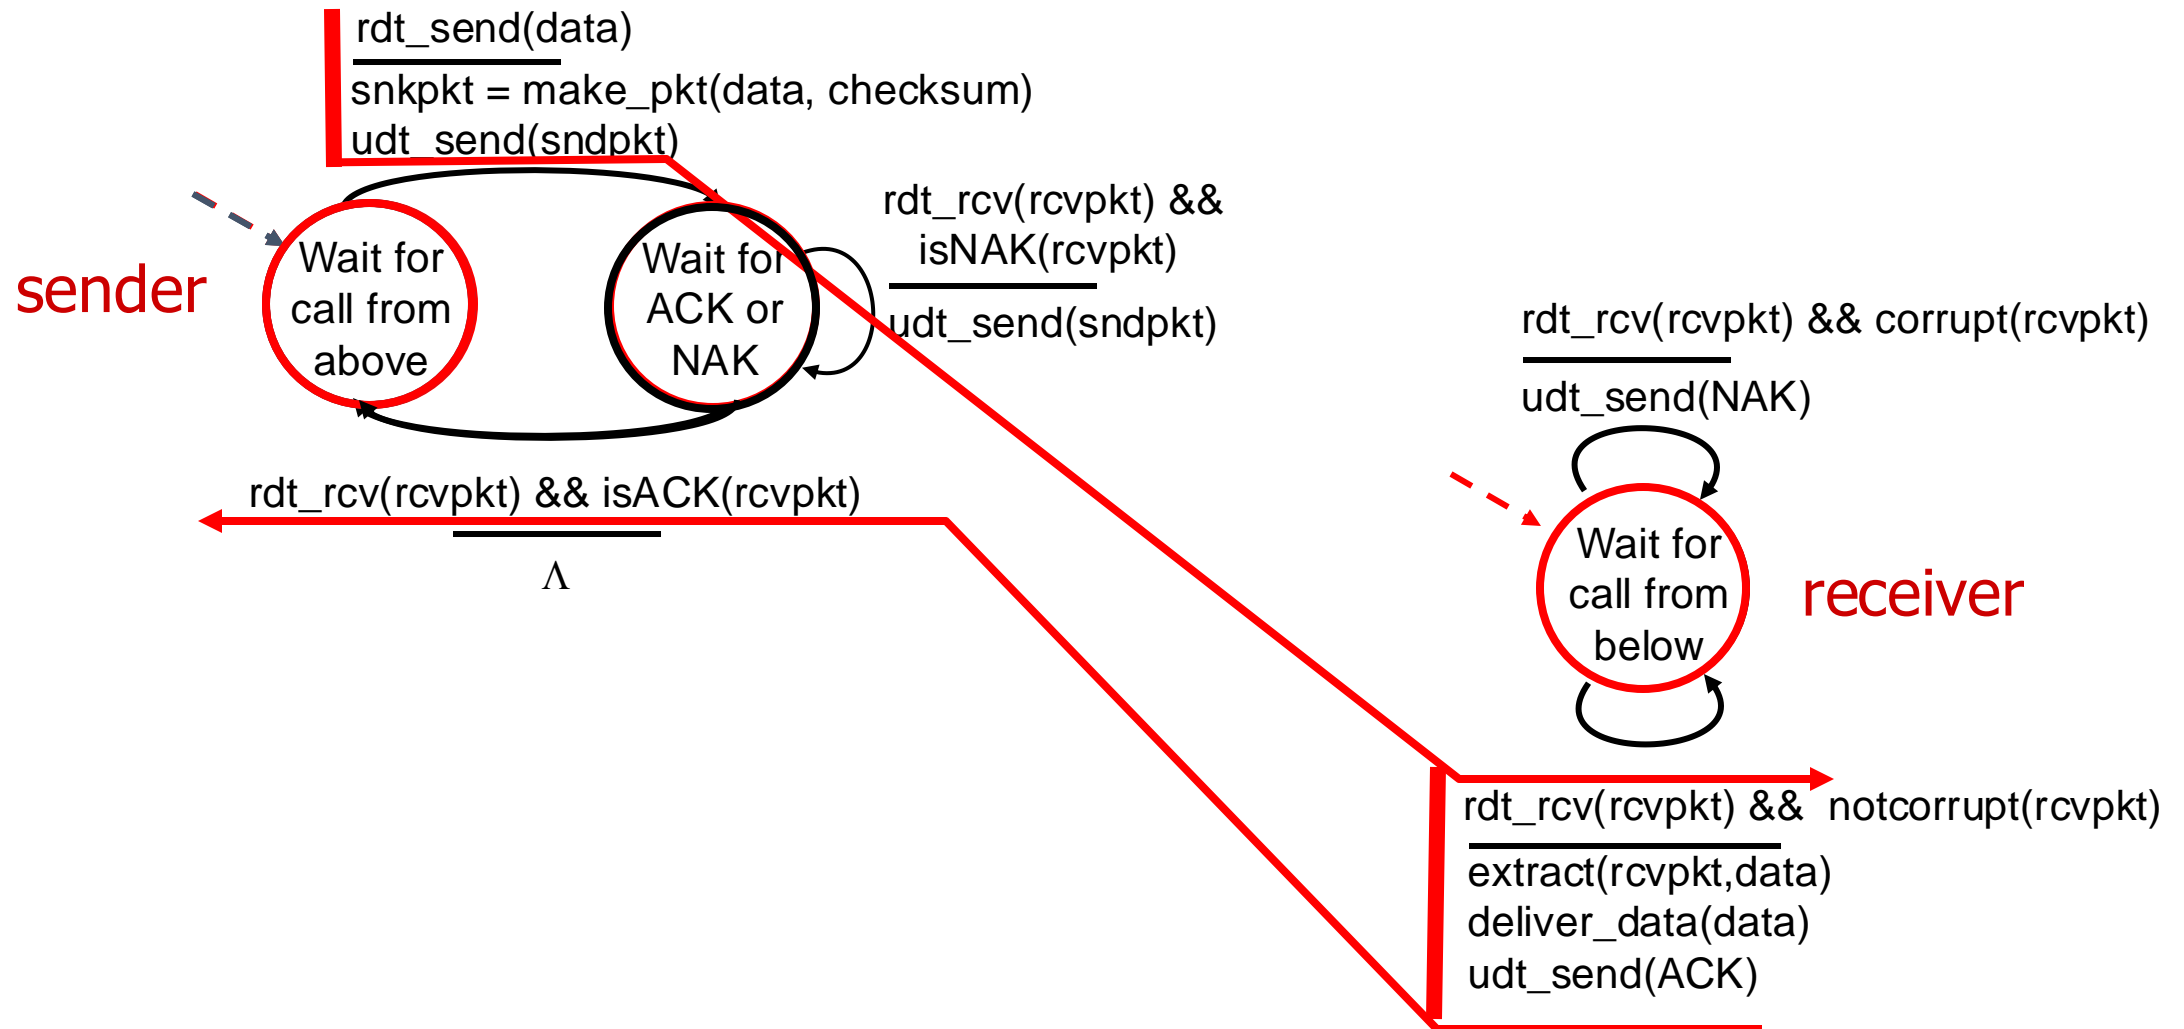

# rdt2.0: FSM specification

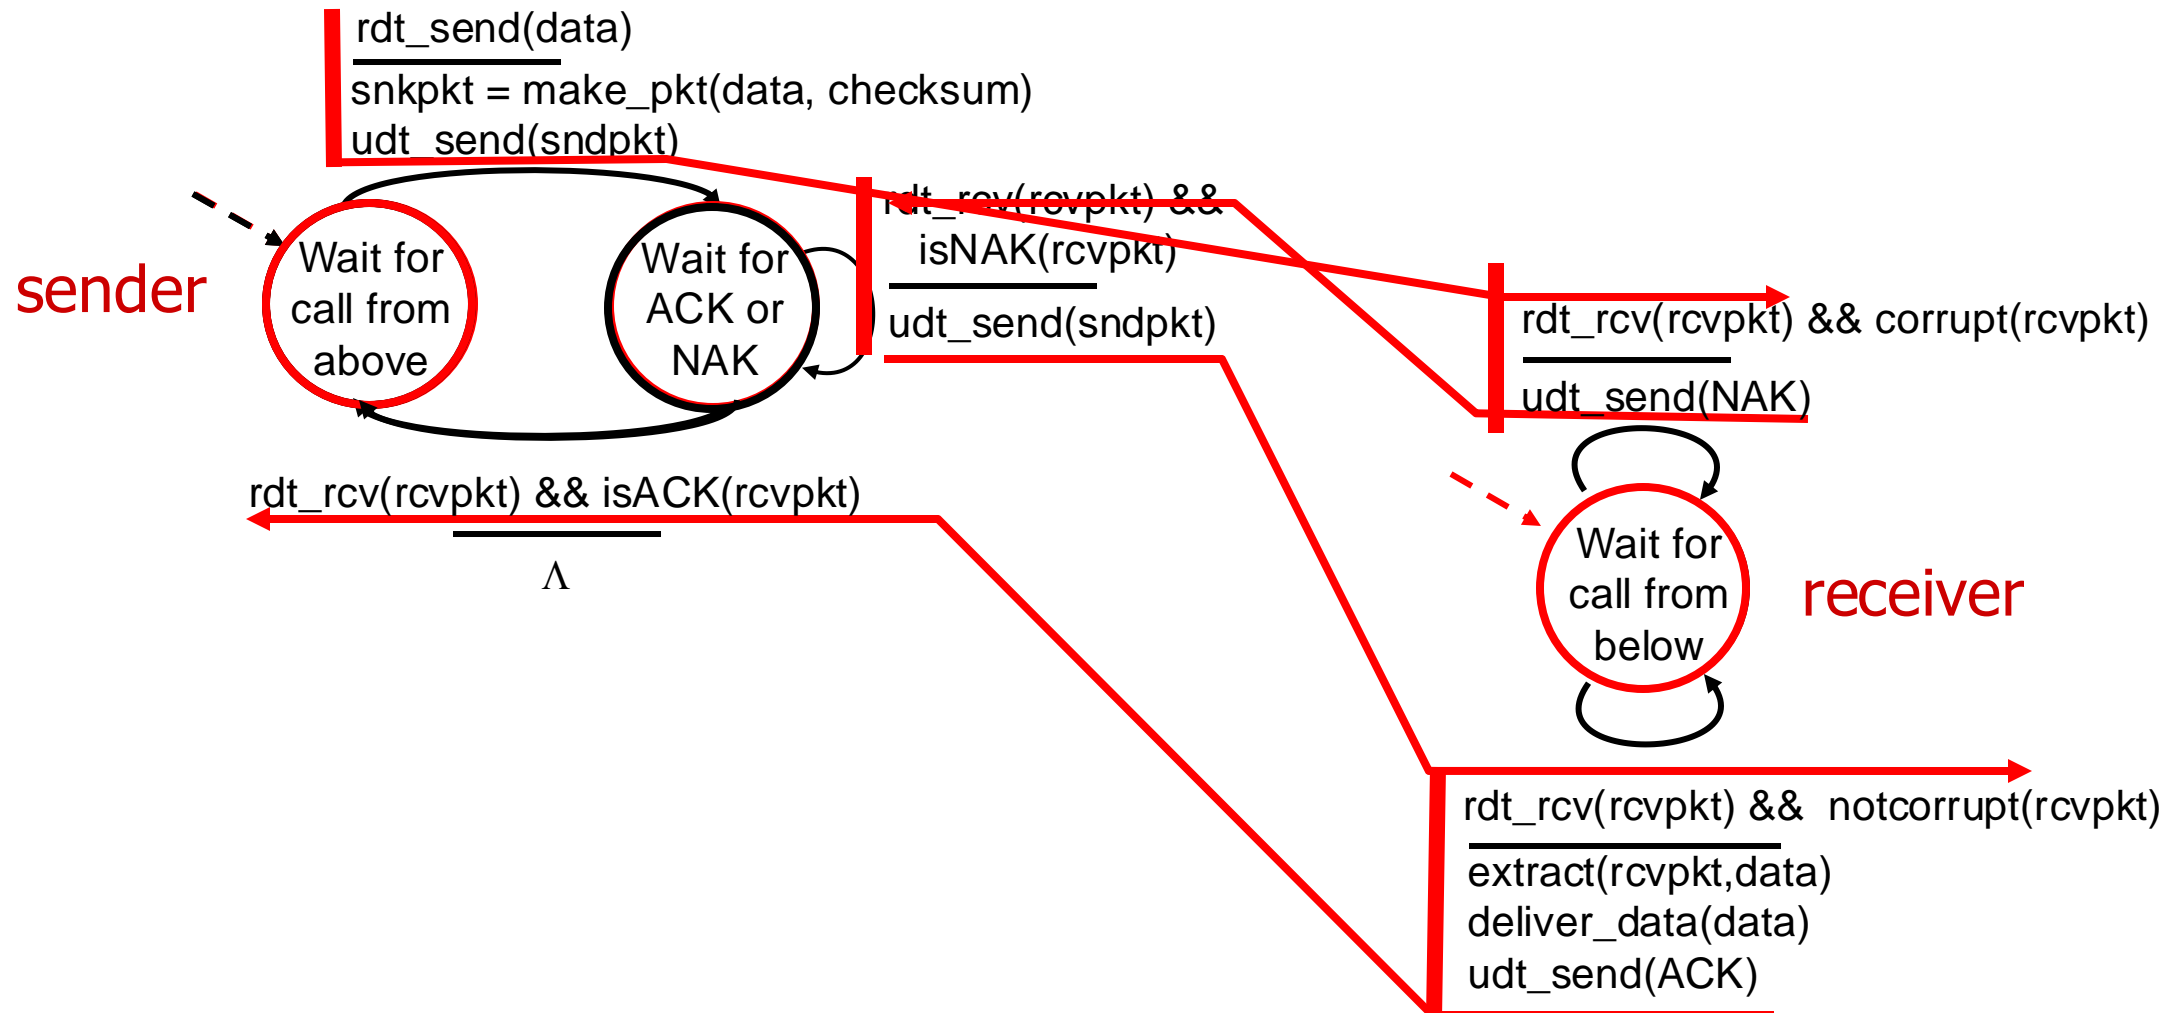

- Note:** “state” of receiver (did the receiver get my message correctly?) isn’t known to sender unless somehow communicated from receiver to sender
- that’s why we need a protocol!

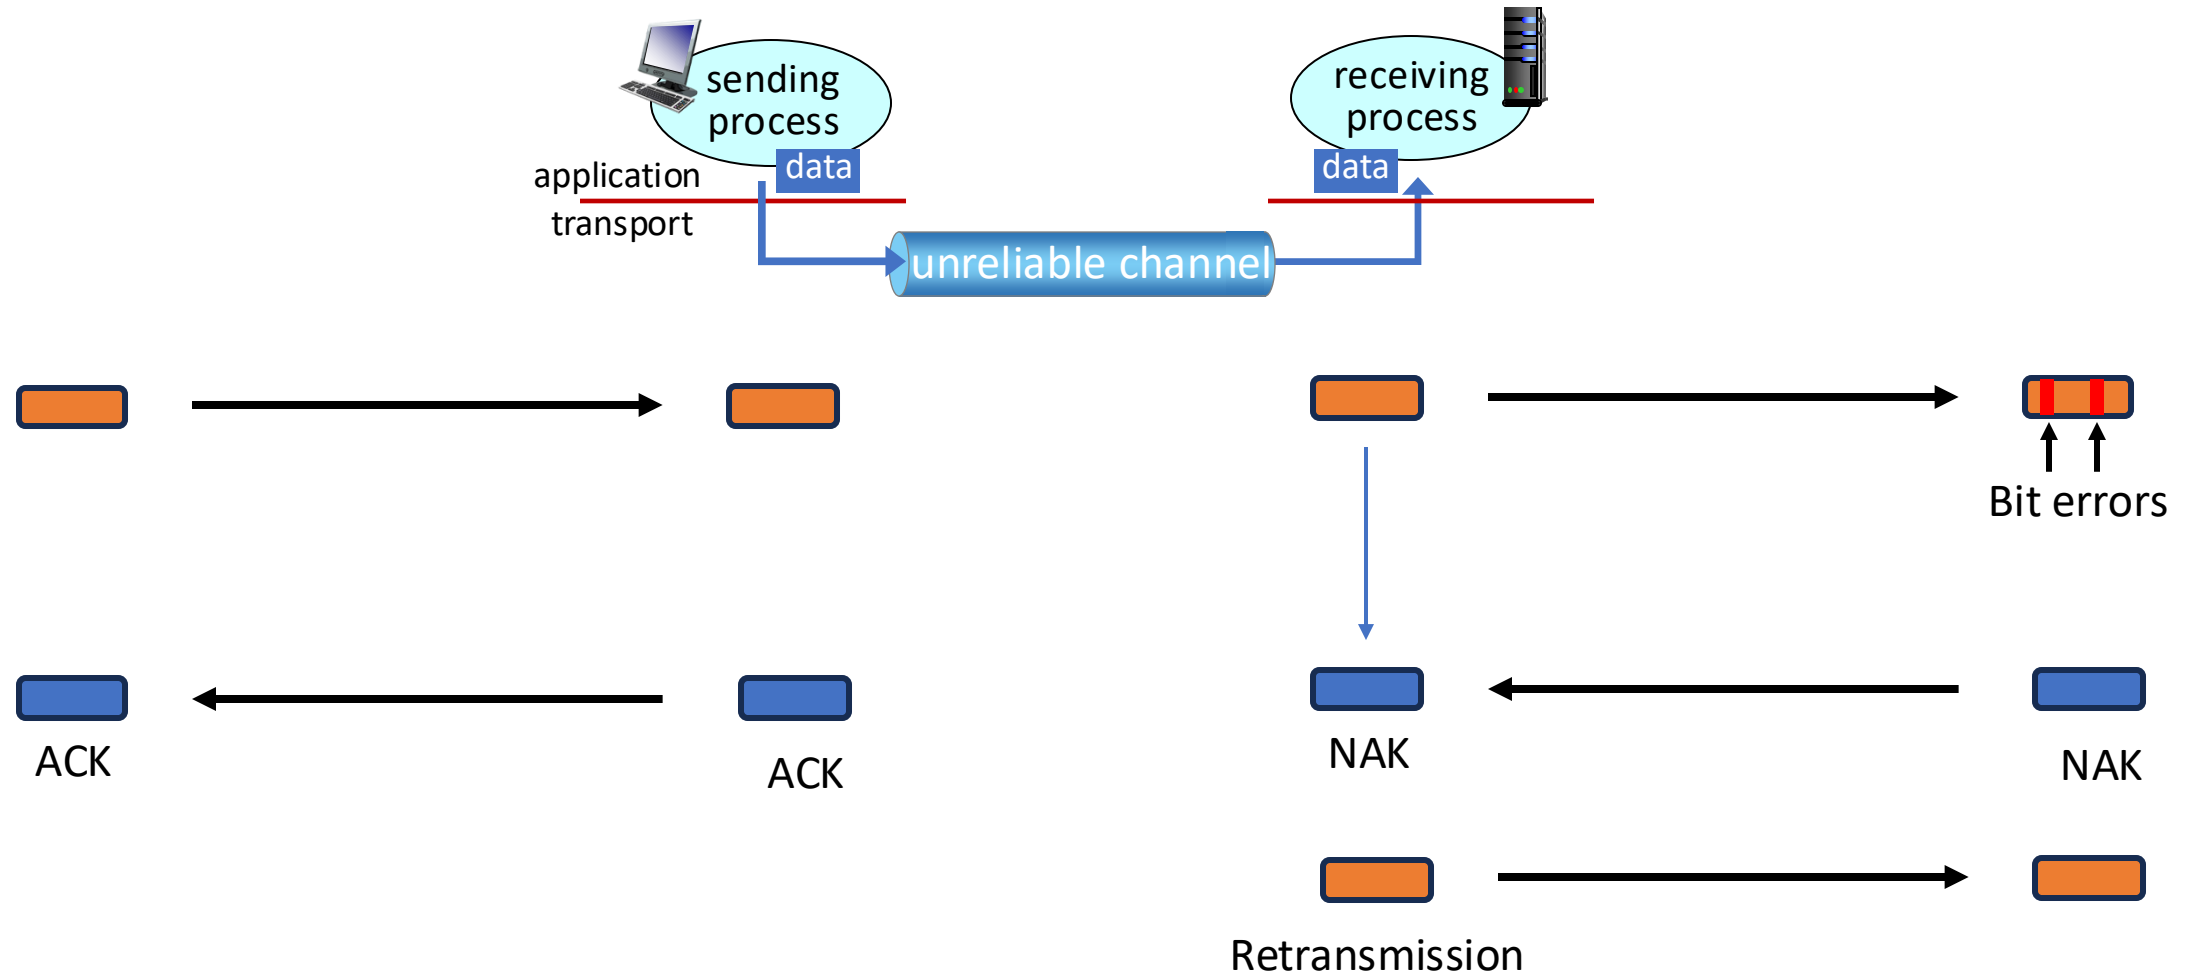

# rdt2.0: operation with no errors

# rdt2.0: corrupted packet scenario

# rdt2.0: no errors VS. corrupted packets

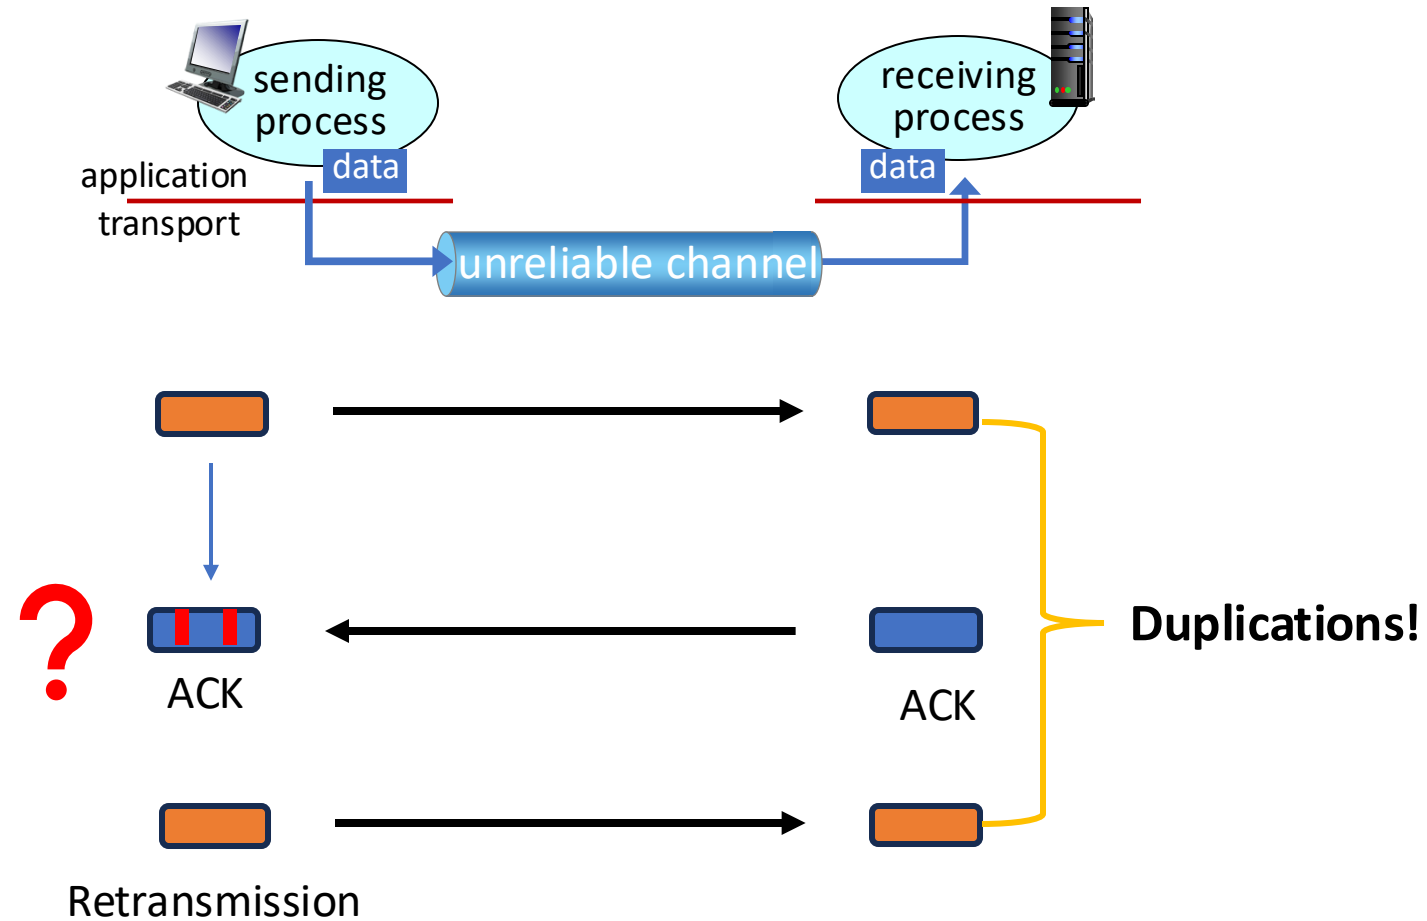

# rdt2.0 has a fatal flaw!

what happens if ACK/NAK  
corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

# rdt2.0: corrupted ACK

# rdt2.0 has a fatal flaw!

## what happens if ACK/NAK corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

## handling duplicates:

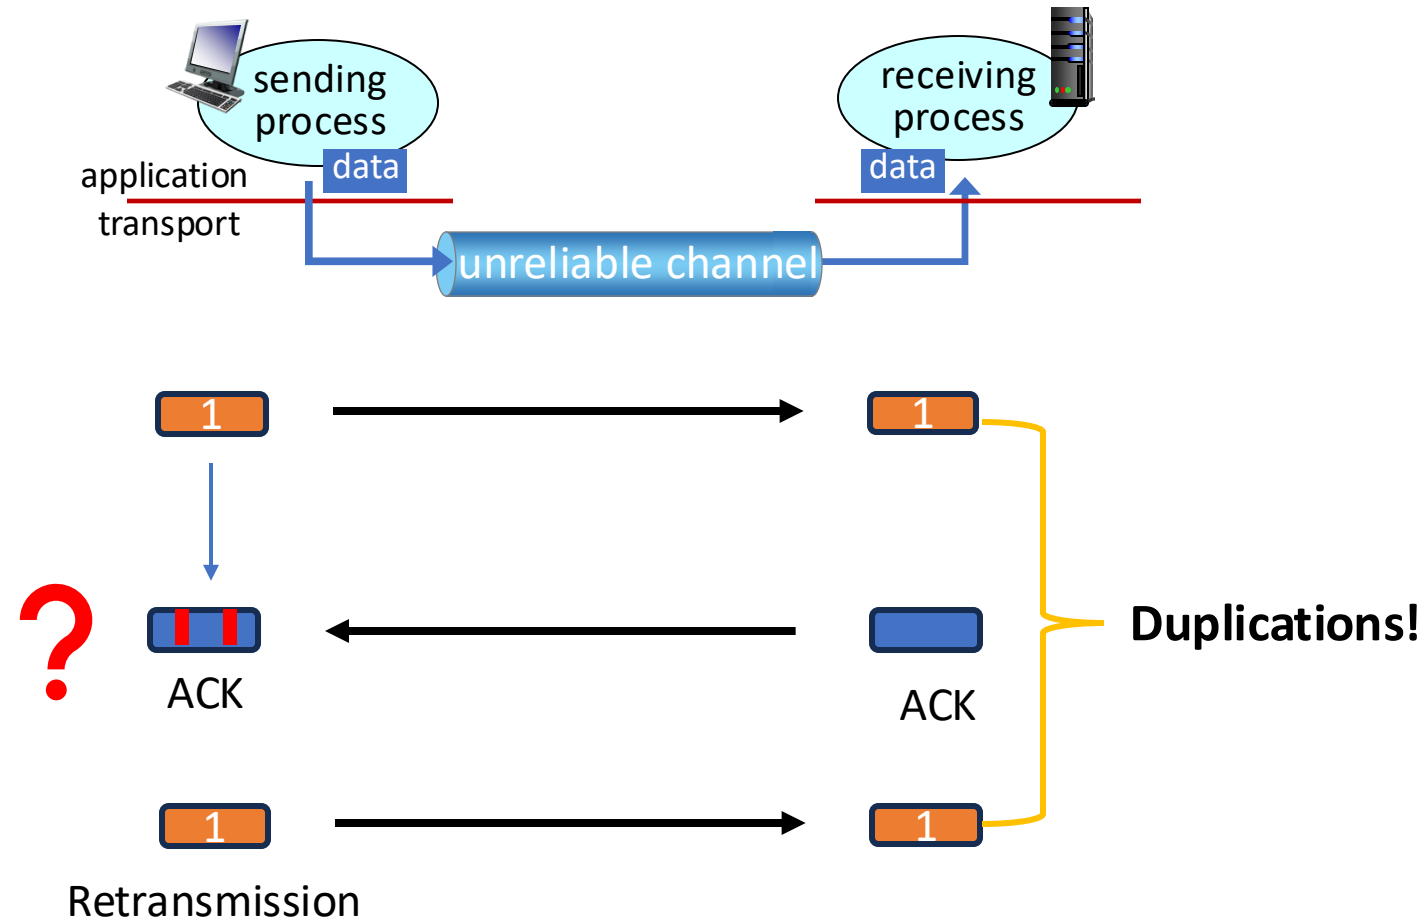

- sender retransmits current pkt if ACK/NAK corrupted
- sender adds *sequence number* to each pkt
- receiver discards (doesn't deliver up) duplicate pkt

## stop and wait

sender sends one packet, then waits for receiver response

# rdt2.0: corrupted ACK

# rdt2.1: summary

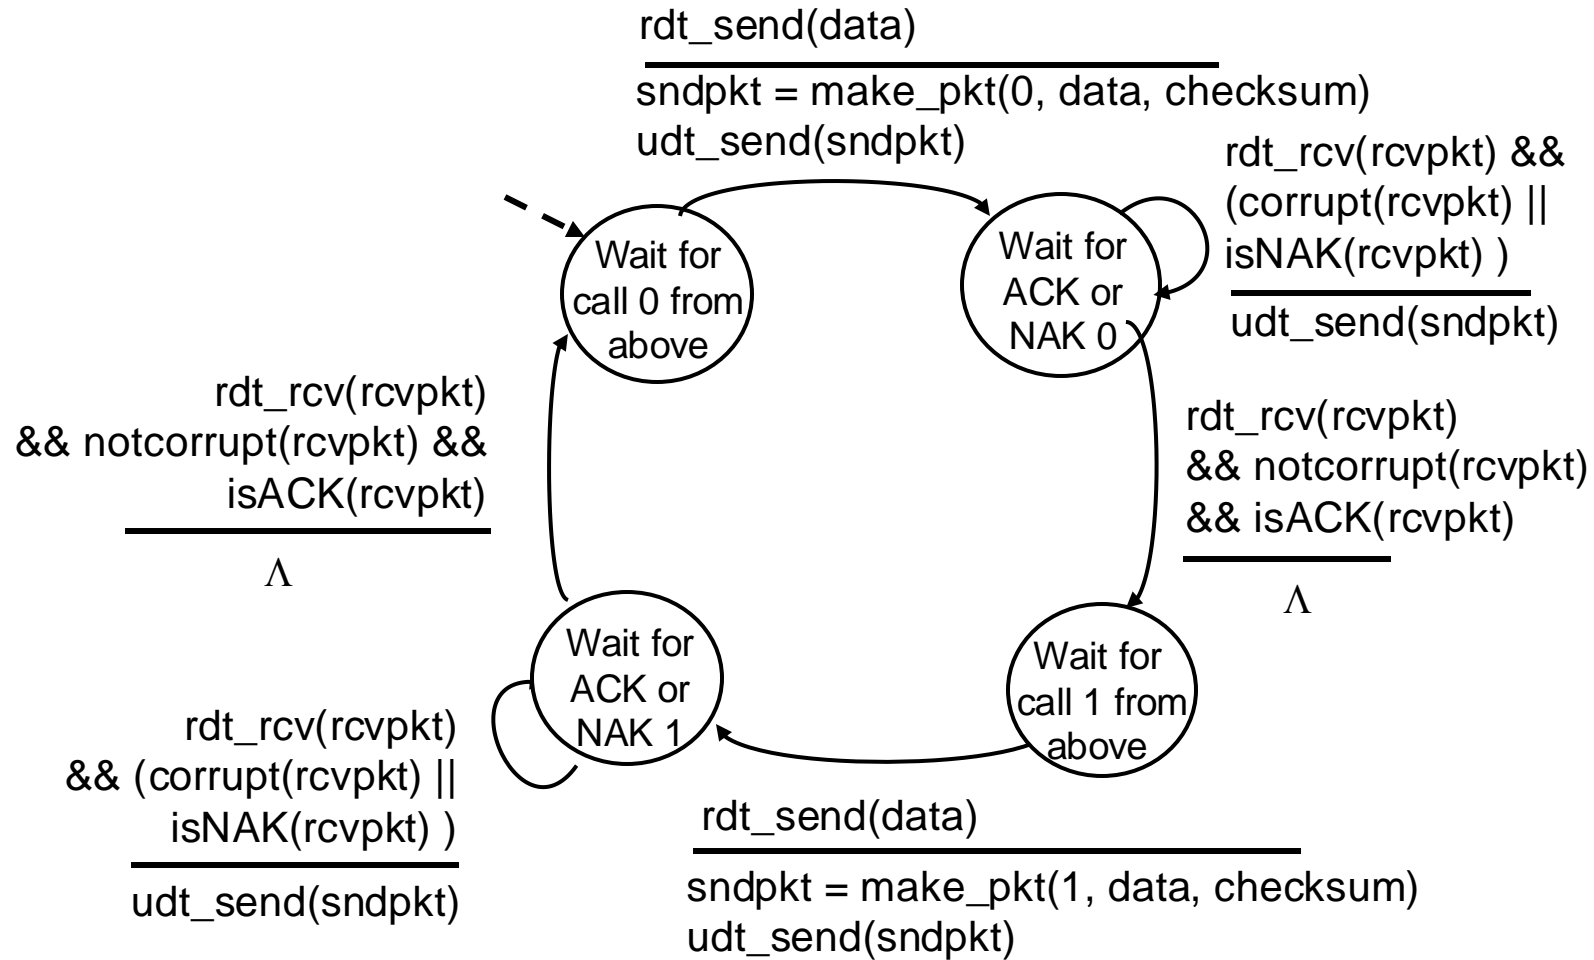

## sender:

- seq # added to pkt
- two seq. #s (0,1) will suffice.  
Why?
- must check if received ACK/NAK corrupted
- twice as many states
  - state must “remember” whether “expected” pkt should have seq # of 0 or 1

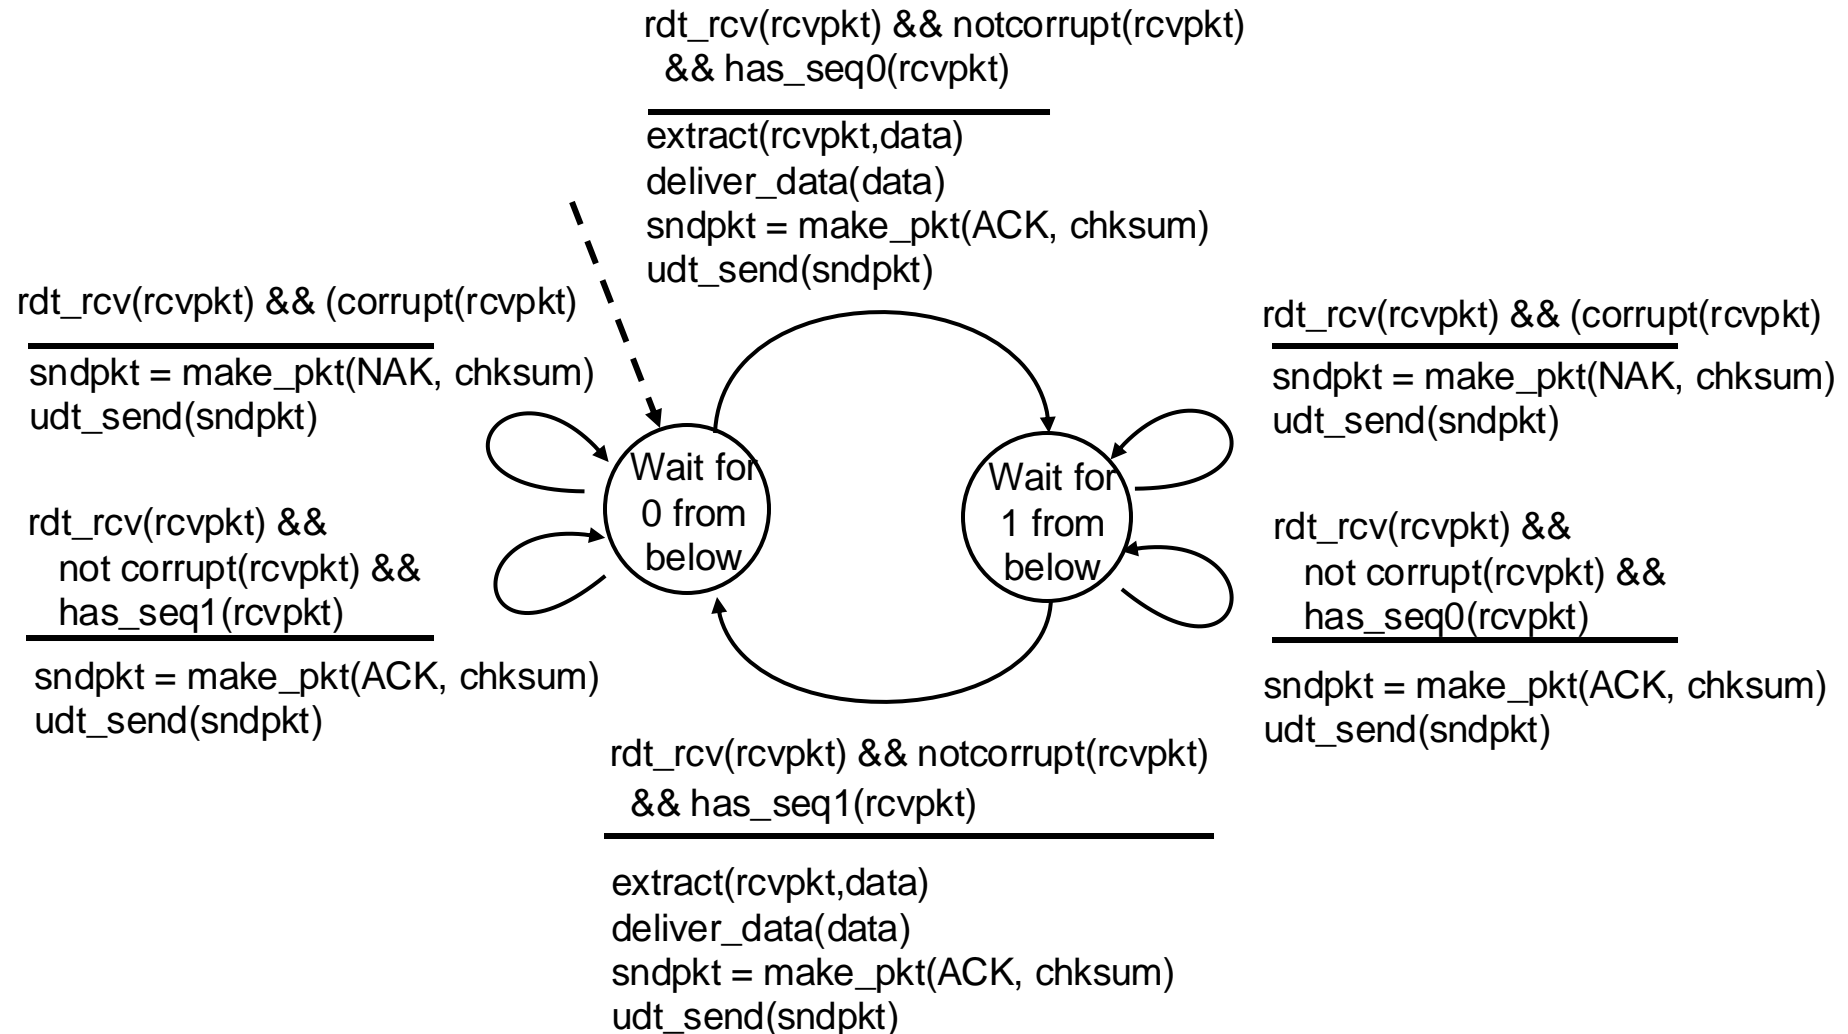

## receiver:

- must check if received packet is duplicate
  - state indicates whether 0 or 1 is expected pkt seq #
- note: receiver can *not* know if its last ACK/NAK received OK at sender

# rdt2.1: sender, handling garbled ACK/NAKs

## rdt2.1: receiver, handling garbled ACK/NAKs

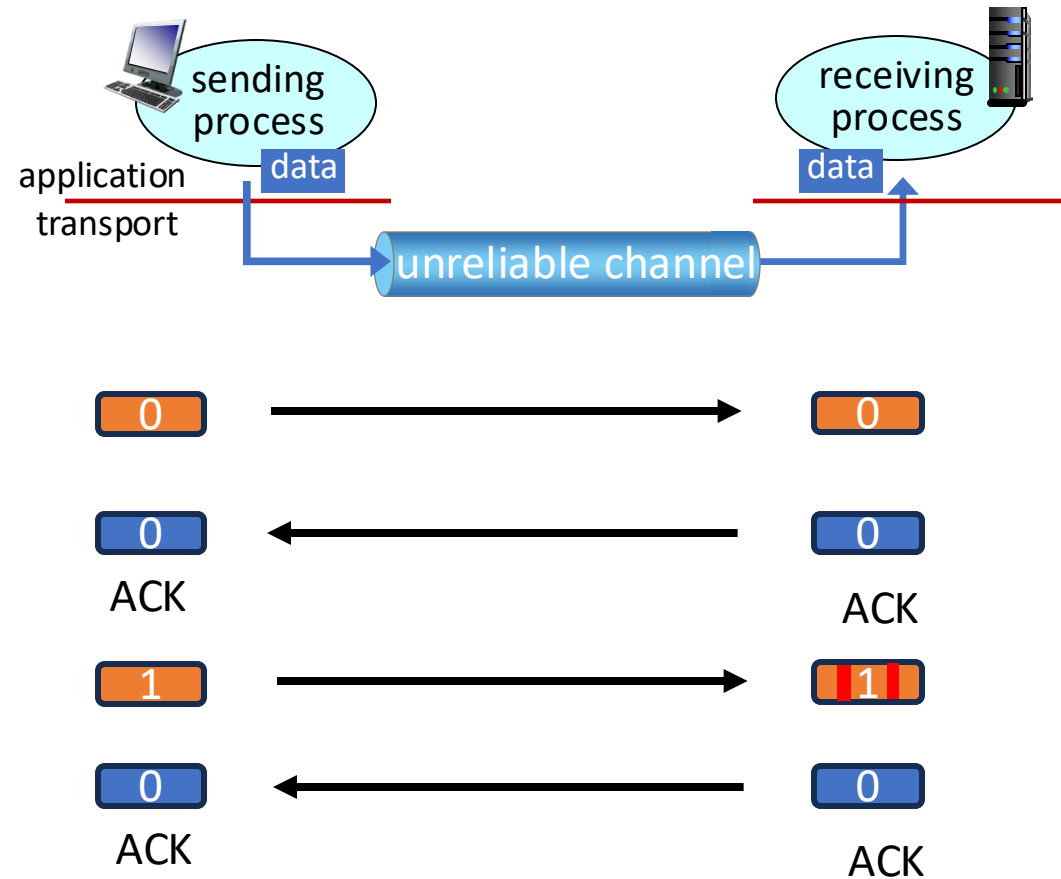

# rdt2.2: a NAK-free protocol

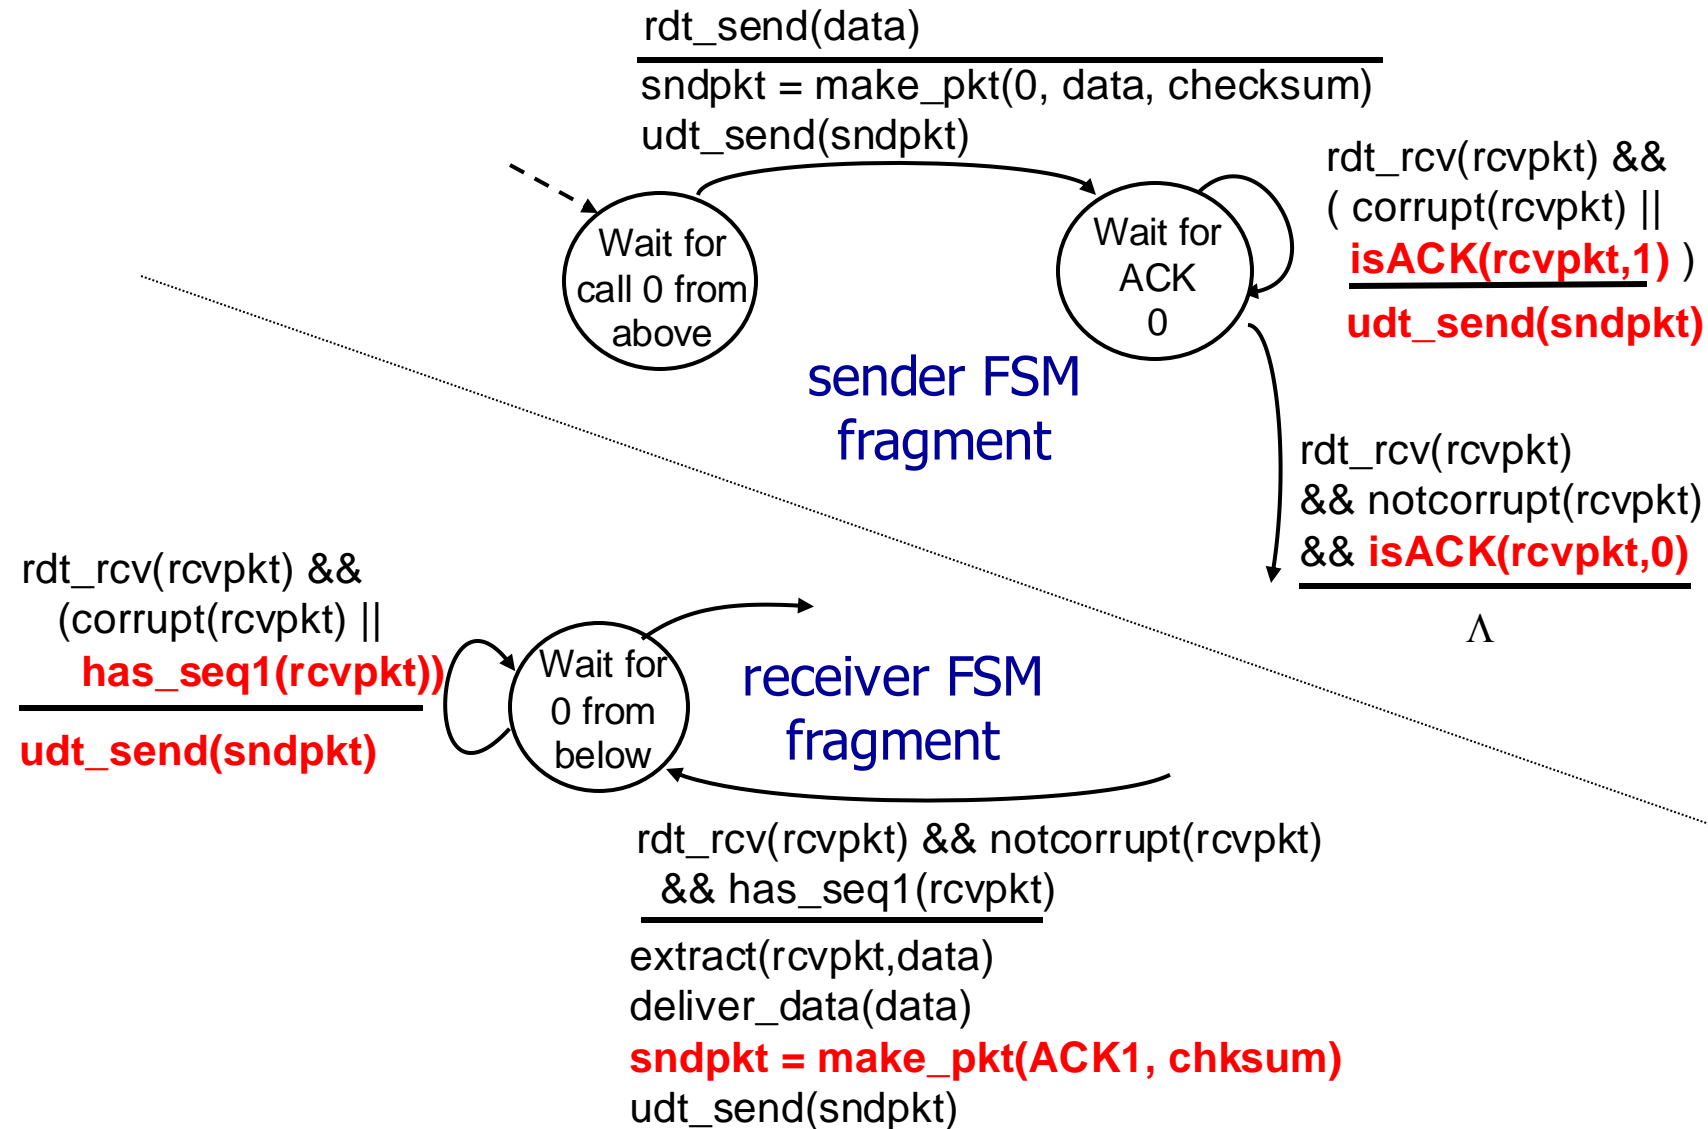

- same functionality as rdt2.1, using ACKs only
- instead of NAK, receiver sends ACK for last pkt received OK
  - receiver must *explicitly* include seq # of pkt being ACKed
- duplicate ACK at sender results in same action as NAK:  
*retransmit current pkt*

As we will see, TCP uses this approach to be NAK-free

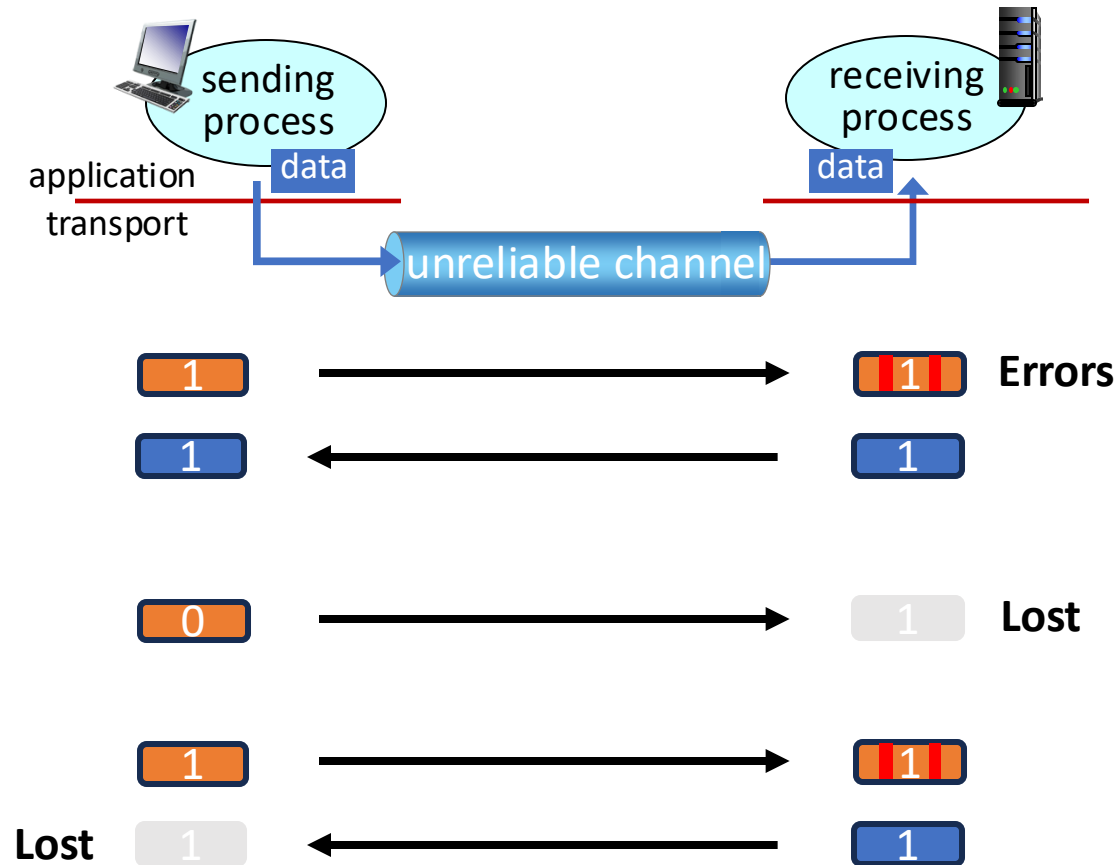

# rdt2.0: NAK-free

# rdt2.2: sender, receiver fragments

# rdt3.0: channels with errors *and* loss

# rdt3.0: channels with errors *and* loss

*New channel assumption:* underlying channel can also *lose* packets (data, ACKs)

- checksum, sequence #s, ACKs, retransmissions will be of help ... but not quite enough

*Q:* How do *humans* handle lost sender-to-receiver words in conversation?

# rdt3.0: channels with errors *and* loss

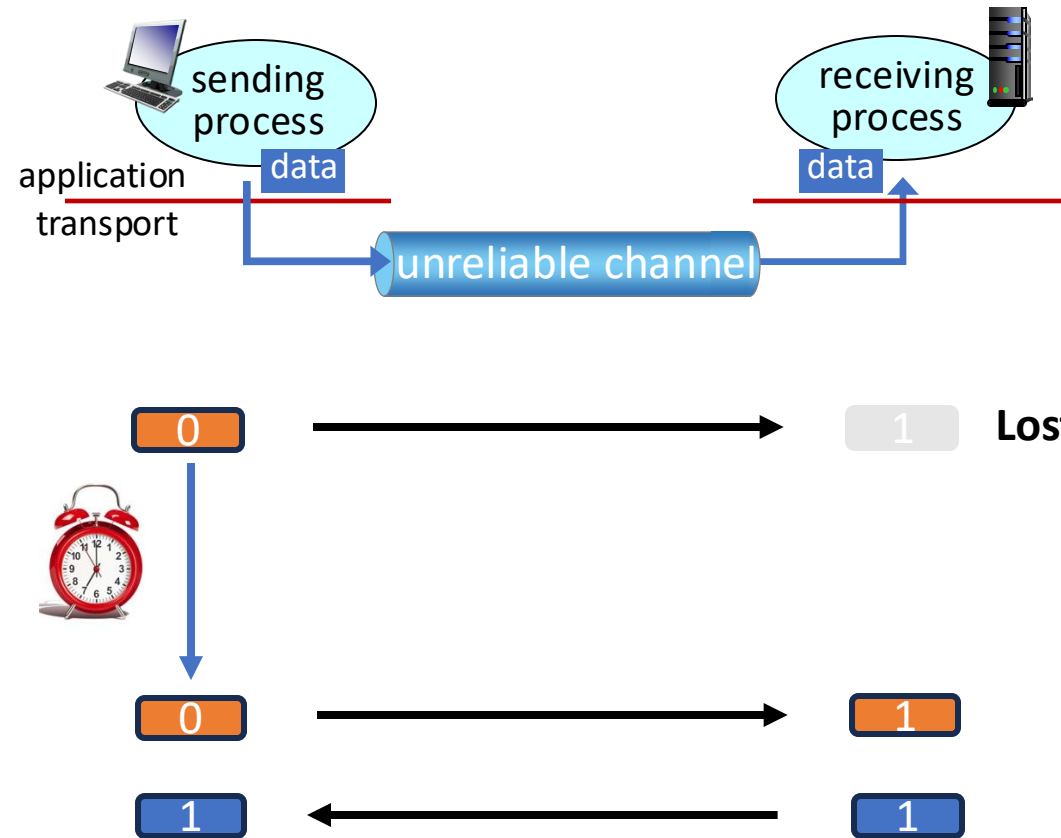

*Approach:* sender waits “reasonable” amount of time for ACK

- retransmits if no ACK received in this time
- if pkt (or ACK) just delayed (not lost):
  - retransmission will be duplicate, but seq #s already handles this!
  - receiver must specify seq # of packet being ACKed
- use countdown timer to interrupt after “reasonable” amount of time

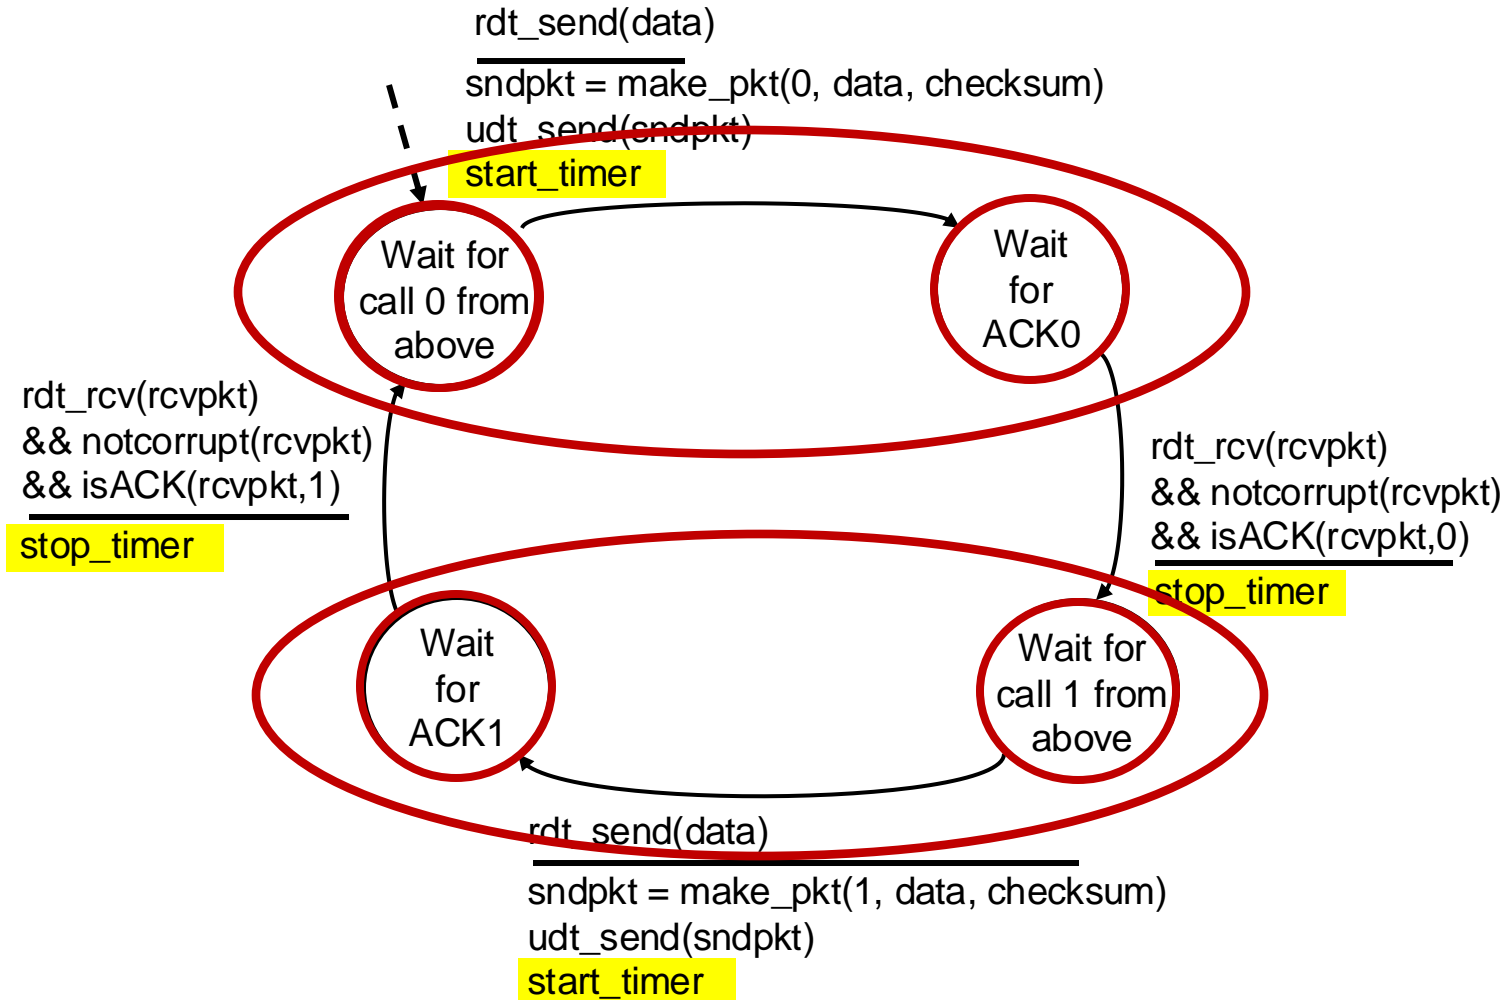

*timeout*

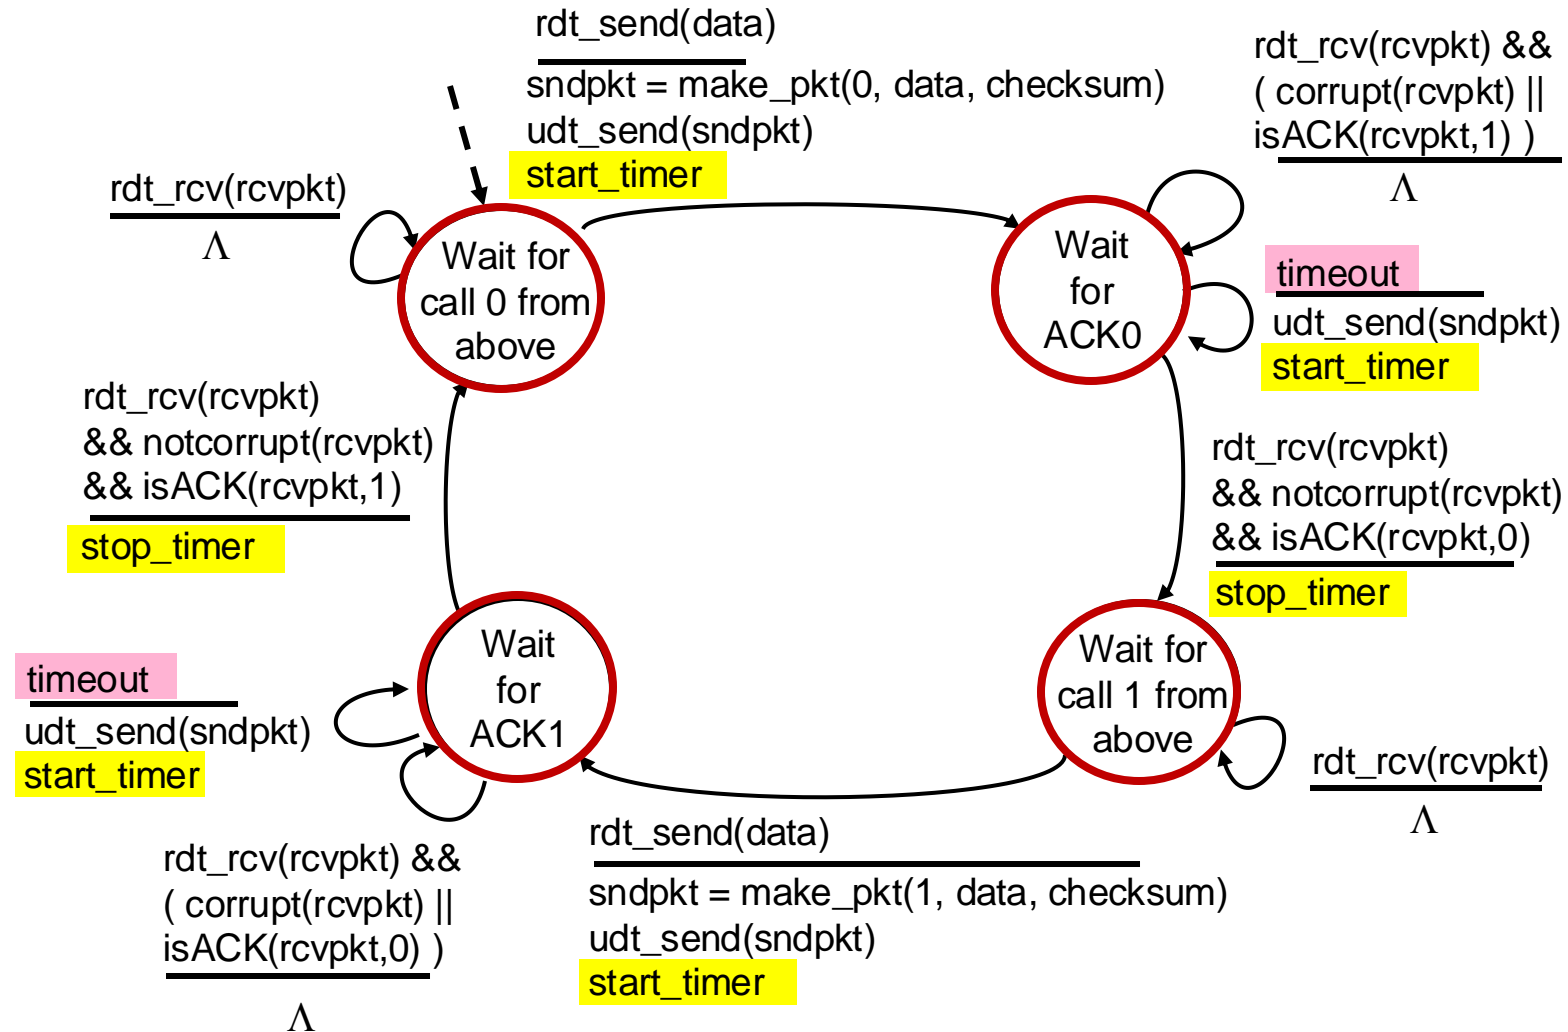

# rdt3.0: channels with errors *and* loss

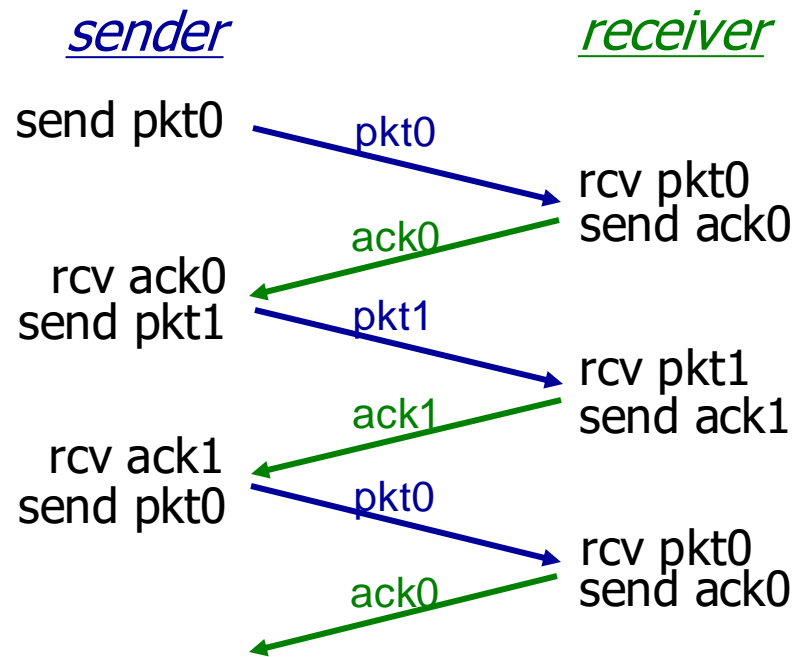

# rdt3.0 sender

# rdt3.0 sender

# rdt3.0 in action

(a) no loss

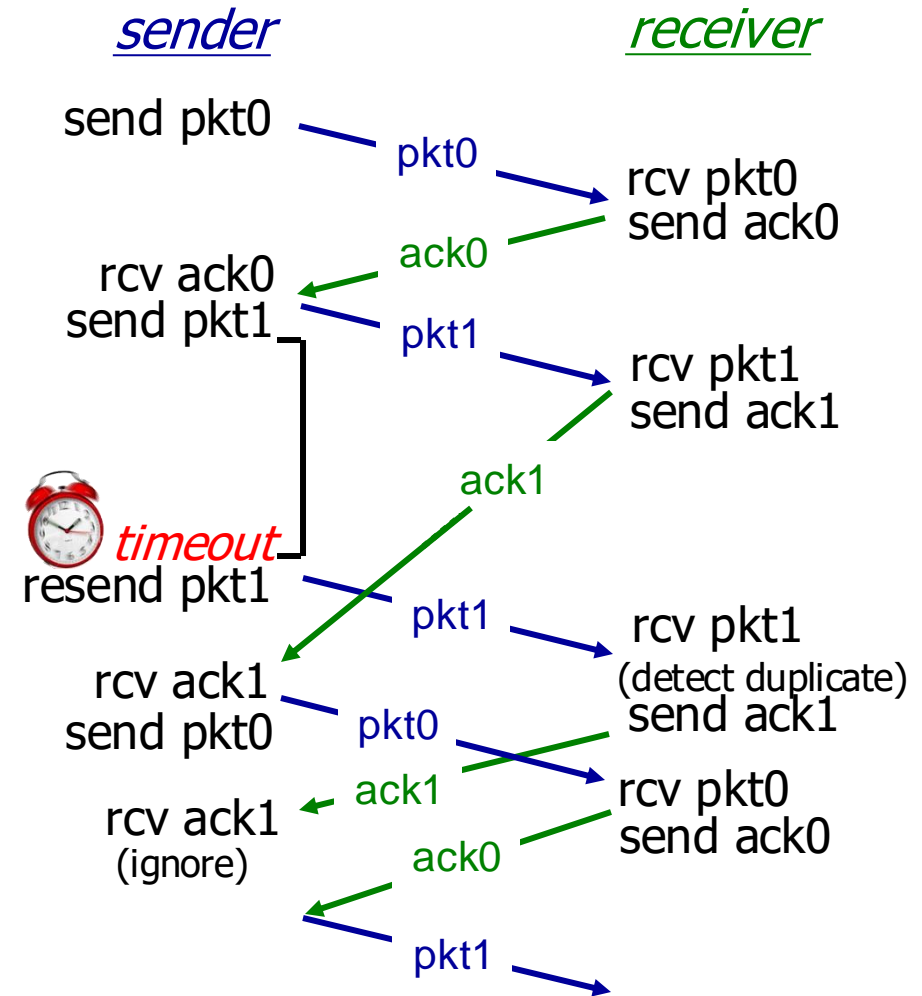

(b) packet loss

# rdt3.0 in action

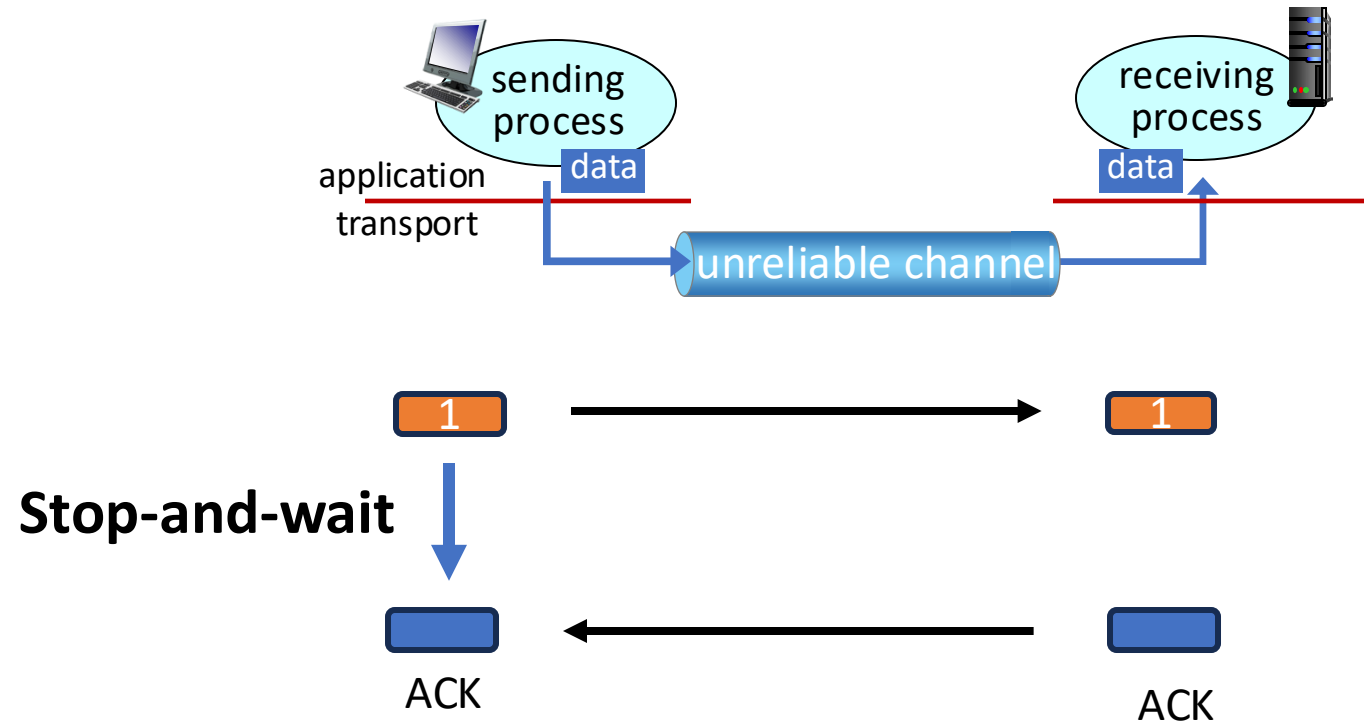

(c) ACK loss

(d) premature timeout/ delayed ACK

# rdt3.0: Efficiency

# rdt3.0: Efficiency

- $U_{sender}$ : *utilization* – fraction of time sender busy sending
- example: 1 Gbps link, 15 ms prop. delay, 8000 bit packet
  - time to transmit packet into channel:

$$D_{trans} = \frac{L}{R} = \frac{8000 \text{ bits}}{10^9 \text{ bits/sec}} = 8 \text{ microsecs}$$

# rdt3.0: stop-and-wait operation

# rdt3.0: stop-and-wait operation

$$\begin{aligned}U_{\text{sender}} &= \frac{L / R}{RTT + L / R} \\&= \frac{.008}{30.008} \\&= 0.00027\end{aligned}$$

- rdt 3.0 protocol performance stinks!
- Protocol limits performance of underlying infrastructure (channel)

# rdt3.0: pipelined protocols operation

**pipelining:** sender allows multiple, “in-flight”, yet-to-be-acknowledged packets

- range of sequence numbers must be increased
- buffering at sender and/or receiver

(a) a stop-and-wait protocol in operation

# Pipelining: increased utilization

3-packet pipelining increases utilization by a factor of 3!

$$U_{\text{sender}} = \frac{3L / R}{RTT + L / R} = \frac{.0024}{30.008} = 0.00081$$
